The CHAIRMAN: Gentlemen—We have come here, I hope, to do a little practical business, at all events for ourselves—therefore I will not make a speech of any great length; but I wish to explain to you the reasons why we have taken upon ourselves—the five members appointed at the half-yearly meeting and the enlarged committee amongst the sixteen of the largest shareholders—to call you together. To put in print all we had to say is not advantageous for a trading company, therefore we thought it better to meet you face to face. The circumstances in which the Company finds itself are somewhat peculiar. At the general meeting of the shareholders—the annual meeting—we passed the report and the balance-sheet; the meeting then was adjourned. Part of the proceedings on that day ought to have been the re-election of two of the retiring Directors, Mr. Watt and Mr. Swaby. At the adjourned meeting a good deal of feeling was shown, and the two Directors were not re-elected; but, by the Articles of Association of the Company, if by any accident Directors are not re-elected at the annual meeting, they stand as members of the Board until the following year. Mr. Watt, therefore, by that Article of Association remains a Director, and Mr. Swaby also remains a Director, though it was his desire at that time to place his resignation in the hands of the shareholders. The result is that, legally, there are only two Directors, Mr. Watt and Mr. Swaby. Probably Mr. Watt found that out, but Mr. Swaby, up to the time he did find that out, had been warned off the premises. You will remember Mr. Swaby held about 2,000 shares in the company, on which he had not paid the 5s. call. Mr. Watt, just before the meeting was held, came forward and paid the unpaid amount, relieving Mr. Swaby of the liability. Please bear that in mind, because it is rather important. He told us himself that he had paid the money due on those 2,000 shares, and as we looked at the balance-sheet we found that all the shares were paid. Mr. Swaby still held 400 shares, which are sufficient for his qualification, and although I am not here to whitewash Mr. Swaby or anybody, I think it is only fair to that gentleman to say that he has given us a great deal of valuable co-operation. When the shares were issued at 5s. each—in order to place as many shares as he could with the public, not to make any profit himself—he subscribed for 4,000 shares; 2,000 he placed amongst the public. He was saddled with 2 000 shares, but as Mr. Watt relieved him voluntarily of that liability Mr. Swaby's liability to the Company ceased, but he still was a Director. When the unpleasantness arose he was ordered off the premises, but as his 400 shares were not cancelled he was still a Director, and Mr. Watt was rather at his wit's end to know how he was to prevent Mr. Swaby from coming. He arrived at the most extraordinary conclusion—that if he cancelled these 400 shares Mr. Swaby would no longer be a Director; therefore he wrote a letter saying that as there was 5s. a share owing on 2,000 shares, therefore the Company had forfeited the 400 shares, and would take them towards that debt, which was not due to the Company, because Mr. Watt had assumed it. It was one of the funniest things that ever came before me. Then Mr. Swaby was ordered off the premises. Then came our meeting, the committee presented their report, and we were told to consult sixteen of the largest shareholders. Then there was a very painful meeting, at which Mr. Watt thought it necessary to have a criminal lawyer on his right and a solicitor on his left, armed with an opinion of the legality of the meeting, and it was dissolved as an illegal meeting. Of course, Mr. Watt was in a difficulty then; there were only two Directors, himself and Mr. Swaby. Probably the solicitor pointed that out. Mr. Watt wrote to Mr. Swaby, saying on reconsideration he had cancelled the cancellation of the 400 shares and restored them to the register, and Mr. Swaby was a full-fledged Director. Mr. Swaby went on the Board again, and there Mr. Watt suggested to him that they had better strengthen the Board. Mr. Swaby said that the sixteen largest shareholders were to consult together, and until that was done they had better do nothing. Mr. Watt said, "As a compliment to you you can propose the first Director." "No," said Mr. Swaby, "I shall get myself into difficulties with the shareholders: I shall propose nobody." He left the Board meeting, and within a few hours afterwards received another letter from Mr. Watt saying he had again cancelled his 400 shares. It is one of the funniest things that has ever happened in the City of London. I may say that it is with a feeling of regret that I have to mention Mr. Watt's name so often; it is solely because Mr. Watt has made himself the Company. The 16 largest shareholders could get nothing from him; he would not recognise that they were appointed at a legitimate meeting. Mr. Swaby was warned off the premises, and his 400 shares are in the air. I had to mention his name to show the position we took up. We thought the proper thing was to ask you to choose five independent Directors. If Mr. Swaby is the bad man that Mr. Watt told us he is, the new Directors can take that into consideration; but he has treated us with such courtesy and kindness all through, besides giving us information which has been of the utmost value, that I do not think the five Directors will find him at all in the way. I would ask you to choose five independent Directors. If you think Mr. Watt a man of such excessive value to the Company that we cannot get on without him, well and good; we do not want to sway your opinion one way or the other. Mr. Goschen said that joint-stock companies did not succeed because shareholders do not take an intelligent interest in their own affairs; we have not till quite recently, and I think we have now seen enough to know that Mr. Watt is the autocrat not of the breakfast table but of the Board table. We should have gentlemen as Directors who are not interested in the Watt dynamo, but in the old Maxim-Weston, which I think shines as brightly as ever. I will not go into the question of office expenses, but you know the offices are rather expensive. I believe that if you have an independent Board this Company will have a good future.

Mr. JACKSON: Mr. Watt, the Chairman, is evidently disappointed and disgusted at the position he finds himself in, but I think we should know whether there is a possibility of his raising an issue which may upset a resolution of this meeting. I think the shareholders are much obliged to you, but they should feel assured that the course you recommend is a legal one, and can be acted upon, and, further than that, can be enforced.

The CHAIRMAN: I can answer that question very simply; it is in accordance with the Articles of Association. An extraordinary general meeting can carry anything. We must have signatures representing 62,400 shares calling on the Directors to summon an extraordinary general meeting. We are quite within our legal powers; the Directors must summon a meeting if we send in the requisition. Though we have no money at our disposal my back was put up a little, and I have taken counsel with my own solicitor all through as to the steps we were taking to satisfy myself.

Mr. JACKSON: Has the Company issued the notice calling this extraordinary meeting?

The CHAIRMAN: This is not an extraordinary meeting, it is a private meeting.

Mr. JACKSON: You will call upon the Chairman to call an extraordinary general meeting in accordance with the Articles of Association.

The CHAIRMAN: That is it.

Mr. NEWTON: I was the one to suggest this meeting, and therefore I may explain the object I had in view. We cannot get a requisition signed by the holders of 62,400 shares without very considerable expense, and we thought it would be much cheaper to engage this room so that those of you who are desirous of assisting the committee in getting signatures to enable us to have a legally constituted meeting can do so. At that meeting we can elect Directors. We cannot elect Directors in this Company unless the gentlemen who will consent to go on that Board have sent in a written statement to that effect to the Company seven days prior to the holding of that meeting. We, the committee of 5 or 21, whichever you choose to call us, could have selected the names of five gentlemen to go on the Board, but it would have looked like a hole and corner selection. I have no desire to go on that Board, and none of my colleagues have; but I have a great desire that there should be put upon that Board five gentle-

Digitized by Google

men who have a knowledge of how to buy a patent and how to sell it, in case of need, and act in the interest of fair play and justice to both the buyer and the seller. We have no faith in Mr. Watt being in a position to buy for us something which he has to sell. It is utterly impossible for Mr. Watt to occupy that position, and yet we are inclined to think he is quite prepared to undertake it. I have lost all faith in any company and in any matter with which Mr. Watt may be connected. I will give you my reasons. At the last meeting Mr. Watt told us very straight from that chair—I am very sorry he is not here because I wanted to say this in his presence, but I say it deliberately in order that his secretary, who is taking notes, may report what I say to him—he told us he had had some sort of communication with Mr. Brown, a retiring Director, which empowered him in some sort of way to elect Mr. Howell in some sort of manner, and Mr. Howell was elected with the concurrence of Mr. Brown. I believed that statement because I believe a gentleman who speaks from the Chair. I believed it until I saw under the handwriting of Mr. Brown a letter to this effect which simply amazed me. I do not think it is a forgery. This is the letter:—

"May 4th, 1888.

"Dear Mr. Swaby: In reply to your letter, which I have just received, I write to inform you that since I retired from the Board of the Maxim-Weston Electric Company (Limited) I have held no communication with any of the officials or anyone connected with the Company respecting its proceedings. I have never been consulted on any matter connected with it. I have not held a share in the Company for the last two months, and have taken no interest in it of any kind. (Signed) JOHN BROWN."

That letter is diametrically opposed to the statement made by Mr. Watt. If Mr. Watt will make that statement to us shareholders, I cannot have faith in Mr. Watt to be in the position to purchase, on behalf of myself and you, a patent of which he is the proprietor. Therefore, it is necessary we should elect five gentlemen to the Board. We do not want to turn Mr. Watt out. (A Voice: "Yes.") I want to do the best for the shareholders. The resolutions will be—

"That, considering the peculiar position of the Board as at present constituted, it is desirable that at least five independent shareholders be elected as Directors."

That is one of the resolutions we propose to submit to a legally constituted meeting. The next will be

"That the following gentlemen" [and then there are five blank spaces] *be elected Directors of the Company."*

We have no object but that you at this meeting should nominate five gentlemen whom you think worthy of trust to negotiate the purchase of the Watt patent, supposing that after they have examined it as business men, and got the opinion of a capable and independent expert as to its merits, it is worth purchasing—

A SHAREHOLDER: Also that it has not been made by the Company's engineers. I dispute Mr. Watt's ownership.

Mr. NEWTON: We do claim that so much of that patent as belongs to Mr. Watt belongs to us, as he was our trustee. I do not want to take advantage of that; I am desirous we should deal fairly, and pay him something for it if he is entitled to it.

A SHAREHOLDLR: What provision is made under the Articles as to the number of Directors?

The CHAIRMAN: They provide for seven, with a remuneration of £500 a year amongst them, but Mr. Watt, as Chairman, is entitled to receive £1,200 a year.

A SHAREHOLDER: Is there any engagement?

The CHAIRMAN: Yes; subject to six months' notice.

After some further discussion, the following gentlemen were selected for the Directorship, namely, Messrs. J. M. Klenck, G. H. Hilyard, Marks, W. Harvest and Couchman.

The CHAIRMAN stated that Messrs. Hilyard and Couchman would retire in favour of two experts as soon as they could be found to take their places.

The shareholders then proceeded to sign the requisition, and the proceedings terminated in the usual manner.

PATENT

SILICIUM BRONZE AND SILICIUM COPPER WIRE.

The best for overhead Telephone and Telegraph Lines,

AND ALL ELECTRICAL PURPOSES.

Hard Drawn High Conductivity Copper Wire.

ROLLED AND DRAWN

PHOSPHOR BRONZE.

PHOSPHOR BRONZE

BEARINGS, BUSHES,

AND OTHER PARTS OF

ELECTRICAL MACHINERY.

SOLE PROPRIETORS of the British, Indian and Colonial Patents,

THE PHOSPHOR BRONZE COMPANY (Limited),

87, Sumner Street, Southwark, London, S.E.

WIRE AND SHEET MILLS: BAGOT STREET, BIRMINGHAM.

Dr. GASSNER'S PATENT

BRY BATTERY

Dr. GASSNER'S PATENT

FOR

TELEGRAPHIC WORK, ELECTRIC BELLS, AND MEDICAL USE.

Possesses all the advantages of a Leclanché Cell, and none of its deficiencies.

Sole wholesale depot for England,

MAYFIELD, COBB & CO., LTD., 35a, QUEEN VICTORIA STREET, LONDON, E.C.

THE NEW BURGLAR ALARM CONTACT (Patent applied for); cannot get out of Order. Rubbing Contact, and Wetproof.

THE NEW INDICATOR MOVEMENT (Patent applied for). Simplicity and Efficiency.

Trade Terms and particulars on application to MAYFIELD, COBB & CO., Limited.

NEW COMPANIES REGISTERED.

AUTOMATIC ELECTRICAL CORPORATION (LIMITED).—This company was registered on the 7th inst., with a capital of £75,000 in £20 shares, to act as undertakers for the supply of electricity for lighting and other purposes, within the United Kingdom and elsewhere. The subscribers are:—

	Shares.
E. J. Hermandez, 7, Liverpool-street	1
T. G. Kostzentein, 27, Phillimore-place, Kensington, secretary	1
T. G. Blanchard, 25, Huntley-street, Tottenham Court-road, accountant	1
D. Doherty, 6, Great Newport-street, W.C., printer	1
E. Guitton, C.E., 8, Canning-place, W.	1
R. G. Upton, Mitcham	1
W. Sherratt, 461, Oxford-street	1

The number of directors is not to be less than three, nor more than 10; qualification, £250 in shares; the company in general meeting will determine remuneration.

LUTHER HANSON AND COMPANY (LIMITED).—This company was registered on the 6th inst., with a capital of £7,500, in 900 Ordinary and 600 Deferred shares, of £5 each, to acquire patent rights in connection with improvements in electric arc lamps, field-magnets, and in dynamo electric machines and motors, now the property of Messrs. Luther Hanson and Charles, of North Bridge Electrical Works, New Bank, Halifax. The subscribers are:—

	Shares.
*Joseph Longbottom, Wood Bottom Dye Works, Luddenden Foot, dyer	20
*Louis Ingham, Salterhebble, dyeware grinder	20
*G. Charnock, Halifax, contractor	20
*Luther Hanson, Halifax, electrical engineer	100
C. Dobson, Halifax, clerk	3
J. R. Farrar, Halifax, solicitor	1
J. Duff, Halifax, chartered accountant	1

The number of directors is not to be less than 3, nor more than 7; the first are the subscribers denoted by an asterisk.

PETROLEUM ENGINE COMPANY OF AMERICA (LIMITED).—A notice of the prospectus of this company appeared in our last issue. The registration of the company was effected on the 6th inst., the nominal capital being £150,000 in £5 shares. It proposes to acquire and work United States patents for petroleum engines, and for such purpose to adopt an agreement between J. J. Revely Humes and Ernest Whitehead. The subscribers are:—

	Shares.
T. T. Curtis, 17, Triangle, Ruby-street, Old Kent-road, cashier	1
G. F. Adams, 152, Fanbridge-road, N., clerk	1
H. F. Adams, 126, Bayham-road, N.W., clerk	1
W. Micklethwait, 34, Millman-street, Bedford-row	1
C. Chilcott, 39, Frederick-street, Caledonian-road, schoolmaster	1
G. F. Tuker, 30, Kerrett-road, Brixton, stationer	1
E. Whitehead, 73A, Queen Victoria-street, clerk	1

The number of directors is not to be less than 3 nor more than 9; qualification, 40 shares; the first are the Duke of Manchester, Sir Hy. Cartwright, Major Alex. H. Ross, M.P.; Wm. Tipping, Esq.; Major-Gen. W. O. Swanston; Robt. O. Ritchie, Esq.; and Joshua Priestman, Esq.; remuneration, £200 per annum for each director, with an additional £100 for the chairman.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended June 15th, 1888, were £4,760.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY.—The directors of this company have declared an interim dividend for the quarter ended March 31st last of 2s. 6d. per share, free of income-tax, payable on July 14th prox.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended June 15th, 1888, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,923.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half month to June 15th, 1888, are £2,931, as compared with £2,792 in corresponding period of 1887.

REMOVAL.—Messrs. Crossley Brothers (Limited) announce that on the 24th inst. their warehouse and office will be removed to their new premises at No. 10, St. Bride-street, Ludgate-circus. Their premises at 24, Poultry will be used as a show room only.

STANHOPE TELEPHONES.

NO CARBON OR OTHER MICROPHONE EMPLOYED.

ARTICULATION ALWAYS CLEAR AND DISTINCT. FULLY GUARANTEED. PRIVATE LINES FIXED AND MAINTAINED.
ASYLUMS, WORKHOUSES AND OTHER PUBLIC BUILDINGS FITTED.

STANHOPE COMPANY (LIMITED), (UNDER LICENSE FROM H.M. POSTMASTER GENERAL) **20, Bucklersbury, London.**

Offices—**WINCHESTER HOUSE, OLD BROAD STREET, LONDON, E.C.**

The principal objects of the Corporation are :—

1. Performing the duties of Trustee, Executor and Administrator.
2. The Insurance of Bonds, Shares and all other Securities lodged with the Corporation against risks of all kinds.
3. The Issue of Warrants and Certificates against Securities deposited, and making and procuring advances on such Warrants.

The Office of Trustee or Executor is to private persons usually a thankless post, involving much anxiety, time and money, and frequently leads to serious actual loss; whilst death, illness and change of residence necessitate frequent fresh appointments, and consequent expense to the parties interested. The Corporation undertakes all the duties of Executor, Trustee or Administrator for reasonable remuneration proportioned to the work and responsibility in each case.

The Corporation insures existing Trustees and Executors against all risks attending those positions, where the business is conducted by the Solicitors to their Trusts under the supervision of the Corporation, it not being the desire of the Corporation to interfere in any way with the duties of the family solicitor.

The Corporation acts as Trustees for the Debenture Holders in Public Companies.

For terms, &c., application should be made to the General Manager at the Company's Office.

GEORGE PEARSON, *General Manager and Secretary.*

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL SCIENCE, INDUSTRY AND ENGINEERING.

No. 528.—Vol. XXI. FRIDAY, JUNE 29, 1888. Price 4d.

NOTES.

In connection with the great exhibition to be held next year in Paris the Société Internationale des Electriciens has decided to take the initiative in convening an International Congress of Electricians "to continue the work of the Congress of Paris held in 1881." The proposal is one which will probably be received with some degree of favour, although we scarcely think it will evoke any marked enthusiasm. The Congress of 1881 had before it a definite programme of pressing importance in determining the nomenclature and definition of the practical electrical units. It is true that the definition of the unit of electrical resistance then arrived at was avowedly of a makeshift character, but even those who at the time were opposed to its adoption will not now seriously propose to upset the established usage. If ever the legal value of the ohm undergoes a final revision it must be at a time when the authorities are agreed not only upon the true theoretic value, but also upon some practical unit incontestably superior to the accepted mercury standard. As for minor questions of nomenclature, it is true that there are many terms in use, both in this country and abroad, which have never received authoritative sanction, but they are not of a character which need to be settled upon an international basis. It would also be a sad pity if the protracted and arduous labours of the Nomenclature Committee of the Council of the Society of Telegraph-Engineers and Electricians were to be over-ruled by an international congress, whose decisions would probably be arrived at after a few hours' hasty consideration. But although we fail to see exactly in what sense "the work of the Congress of 1881" can be "continued" in 1889, yet it is impossible to doubt that an international assembly of the representatives of electrical science could be held without producing a marked effect upon the progress of the age, both in science and in industry.

Our reference to the mercury standard leads us to mention that the *Comptes Rendus* of June 4th contains a paper by M. H. Wuilleumier, describing a redetermination of the ohm by a method due to M. Lippmann. We need not now go into details, as we hope shortly to find room for the text of the Paper, but meanwhile it may be stated that M. Wuilleumier arrives at the conclusion that the length of the column of mercury of 1 square millimetre section, whose resistance represents the ohm, is 106·27 centimetres. This gives for the value of the legal ohm, 0·9979 *true* ohm, instead of the usually accepted ratio of 0·998, a difference which is substantially a verification of the previous estimates.

Returning for a moment to the prosposal of the Société Internationale des Electriciens, an additional reason may perhaps be found for wishing success to the project in the fact that the Society has hitherto scarcely fulfilled the expectations of the founders, and indeed has done nothing to justify its lofty style and title. So far as its actual proceedings are concerned, it has long since degenerated into a purely local society; and although it is difficult to see how this could well have been different, yet it might at least have been expected that as the only purely electrical society in all France it would have maintained a leading position in its own department. This, however, is not the case, and the most brilliant and interesting contributions of the French *savants* to electrical science still find their way into the *Comptes Rendus* of the Academie des Sciences, or into the *Bulletin* of the Société de Physique. We venture to think that if there be no prospect of the further development of the Society in justification of its title, the "International" status should be abandoned as misleading.

The number of the *Transactions* of the American Institute of Electrical Engineers which is now to hand contains the report of the discussion on the important Paper by Mr. J. W. Howell on the "Maximum Efficiency of Incandescent Lamps" (see *The Electrician*, Vol. XX., p. 754). The discussion does not add very much to the facts already in our possession, except perhaps in one particular—namely, that the lamps were run direct off the dynamo machine, and not from secondary batteries. We have nothing to say against this procedure, which, indeed, is likely to give results more in accord with average practice, at any rate in America; but the reasons which induced Mr. Howell to discard the more convenient battery will be read with some surprise. He says: "I have had a good deal of experience with lamps on storage batteries, and I am perfectly willing to be criticised when I make the statement that the pressure on the storage battery, as ordinarily installed, varies, I think, five times as much as it does on the average dynamo plant; and that the life of lamps on a storage battery plant, as ordinarily installed and handled, is very much lower than it is on the average dynamo plant, due to nothing else than the simple impossibility of keeping their pressure anywhere." The sentences which follow leave us doubtful whether or not Mr. Howell does not intend to confine

Digitized by Google

his statement to the case where the lamps are being run while the battery is being charged. In any case we find it difficult to reconcile these views either with practice or theory as understood in this country.

THE forthcoming trials of electric motor traction by the Metropolitan Railway Company will be watched with the greatest possible interest both by engineers and electricians and by the public at large. It is hoped that a beginning will be made in October or November next, but considering the supreme importance of the case and the necessity that nothing shall be be left undone to ensure success, we shall not be surprised if a little further delay arise. At the same time we understand that the Railway Company are anxious to have the system in full operation by the time their extension to Pinner, Rickmansworth and Chesham is in operation, since it is their intention to employ the discarded engines upon this service. If the new line be further extended to Aylesbury and Birmingham—as is already proposed—the whole of the engines at present in their possession would find full employment thereon, and the underground lines could be worked—so far as the Metropolitan Company is concerned—entirely by electric traction. It will therefore be seen that the question has been taken up at a favourable juncture, seeing that new engines of one or other type would in any case have to be ordered shortly. The engines at present in use are of 450 horse-power, but it is proposed that the electric engines shall be capable of developing not less than 600 horse-power each. It is also proposed that the storage capacity shall be sufficient to take the train twice round the inner circle—which is equivalent to about 1½ hour actual running. What this means in regard to dead weight we do not care at this moment to specify, but that it will be something considerable is very obvious. It is this question of dead-weight (amongst several others) which in the case under consideration has already led us to express a decided preference for the system of working direct from the dynamo, and in our issue of April 27 (p. 705) we proposed a method of experimentally introducing either a conduit or an overhead conductor system, which involves no interference whatever with the ordinary traffic of the line. However, we do not pretend to have had the subject so fully under consideration as the engineers who are responsible for the present scheme, and we must believe that they are justified in preferring the use of secondary batteries, at least for the experimental trials. The final decision as to the methods best adapted to the special circumstances may well be postponed until the railway company has had time to familiarise itself with the working of the new locomotives, and if desirable or necessary the conversion of the system could then be effected without serious additional cost.

WITH regard to the economical side of the question, it is interesting to know that the railway company will be able to save the wages of one man on every train. The starting, brake, and resistance levers or switches can, of course, be managed with the greatest ease by one man; but as it is scarcely safe to have less than two persons on the engine, it is proposed to let the front guard ride with the driver. The wages of the stoker will thus be saved.

IN connection with electric traction, one of the most vital considerations is the choice of suitable gearing. For some time past a tendency has been shown to adopt steel chain gear with sprocket wheels. Very excellent chains are now to be obtained for this purpose, and the arrangement has an advantage over the various forms of toothed gearing in taking jolting strains off the motor. At the same time, for the heavier class of work it has long been recognised that some form of gearing in which the ratio of armature speed to speed of driving wheels is variable is a great desideratum. Various forms of frictional clutch-gearing have been designed for this purpose, but—with one remarkable exception—they have in all cases involved loss of power, with accompanying wear and tear, and the possibility of increasing the useful effort by diminishing the speed has not been attained. The exception we refer to is that of the extremely ingenious "epicycloidal gear," designed by Mr. WORBY BEAUMONT, and described by him in a Paper read before the British Association in 1886. For some reason or other—chiefly, perhaps, owing to the modesty of the inventor—this device has not met with the attention it deserves. In another column of the present issue will be found a detailed description of the arrangement, which we commend to the careful attention of all engineers who are interested in electric traction.

IT is to be hoped that Lord CARNARVON'S warning with regard to the free use of our fortified ports by foreign war-ships may be applied also to our submarine telegraph cables and military land lines. The imprudence which Lord CARNARVON so much deprecates has, indeed, only one excuse, namely, that it arises from a generous characteristic of the English race, and from their ineradicable disbelief in the possibility of war until hostilities have actually commenced. It is just possible, however, that in the present temper of the public a word of caution may not be thrown away; and we venture to point out that the routes of our submarine cables, their landing places abroad as well as at home, and the track of our land lines, subterranean or overhead, are all perfectly well known to every war office in Europe. This is not a satisfactory state of things; and we call attention to it because it is capable to some extent of being remedied, if the British Government has a mind to.

A LIEUTENANT-GENERAL of the Royal Artillery has complained in the *St. James's Gazette* of the inefficiency of the flag-signalling by Morse code which prevails in the British army, and which he alleges cannot be learnt except with great difficulty, or remembered except with constant practice. He suggests as a substitute a divided alphabet, with so many "wags" to the right for the first half, and so many to the left for the other half. We should not have noticed this very crude proposal—which would in practice be much slower and not so simple as the author imagines—only for its coming from a military man of high rank, although now retired, and the influence it may possibly have in military circles. Speaking with knowledge, we deny every one of the General's allegations, except, perhaps, that the Morse code is not so well known in the army as it ought to be. Praiseworthy efforts are now being made to extend and perfect this knowledge, not only in the army but

Digitized by Google

in the navy, and we should be sorry to see these good intentions discouraged. As a matter of fact, the Morse code can be learned in half an hour. To use it requires practice, for which the army has plenty of leisure; and when once thoroughly mastered, the code cannot easily be forgotten, especially when supplemented, as flag-signalling ought to be, by electric signalling with the Morse key. Telegraphists make the best flag-signallers, the Post Office Volunteers supplying a contingent who can beat the regulars in this particular off their own ground. The moral of this is that army flag-signallers should all be made to learn to work the telegraph. A secret code is as applicable to the Morse system as to any other.

THE extraordinary general meeting of the shareholders of the Pilsen-Joel Company gave rise to some very lively proceedings, but not at all livelier than was fully anticipated. Our issue of April 20th last may be consulted by anyone desiring further information as to the recent history of this company. We have every reason to believe that under proper management the Central Stations owned by this company might become prosperous and paying concerns, and it is a thousand pities that the policy of the directors should have been directed to any other purpose than that of the straightforward development of their business. On the whole, we think that the shareholders may be congratulated on the fact that the efforts of the directors to effect a sale have not yet proved successful. The Board has now been strengthened by the appointment of a committee (containing some practical men) in conjunction with whom the future policy of the company will be thoroughly considered.

WE furnish, in another column, a report of the POSTMASTER-GENERAL'S reply last week to the deputation which waited on him in reference to the now abandoned Bill of the United Telephone Company. This report will be found to differ materially from that which has appeared in the daily papers. In several journals the POSTMASTER-GENERAL was made to refer explicitly to the position which the proposed County Councils would occupy in regard to the question of overhead wires. We have reason to believe that he made no such reference.

Lighting Tender.—It has been decided to call for tenders, in Sydney and Melbourne, for lighting the town of Young with electricity.

Selby.—The Local Board of Health at Selby are advertising for tenders for lighting the streets of that town by electricity. Particulars will be found in our advertisement columns.

City and Guilds Technical Institute Old Students' Association.—On Wednesday evening last this association gave a highly successful smoking concert at Anderton's Hotel, Fleet-street.

Sale by Auction of Post Office Telegraph Apparatus.—We would call the attention of our readers to a sale of Government telegraph apparatus, the announcement of which will be found in our advertisement columns.

The Claude Telegraph.—The Paris-Lyons and Mediterranean Railway Company have decided to try the Claude system of telegraphy, which has given such good results on the Government lines.

Telephone Exchange Burned Out.—The *Electrical World* states that the Telephone Exchange at Thirty-ninth-street and Sixth Avenue, New York, was burned out on the 23rd of May, through a cross between the telephone and electric light wires.

The Sawyer-Man Lamp.—We learn that Mr. Henry C. Davis, the president of the Sawyer-Man Electric Company of New York, is now in London, and has made proposals to several firms to supply incandescent lamps to the extent of half a million a year.

"The Electric Transmission of Energy."—We are pleased to see that the admirable work by Mr. Gisbert Kapp on "The Electric Transmission of Energy" has been translated into French by M. E. Boistel, and is published by the Bibliothèque Internationale de l'Electricité.

The Lighting of the Leeds Fine Art Gallery.—The Electric Lighting Committee of the Leeds Corporation recently visited the establishment of Messrs. Greenwood and Batley, in Armley-road, Leeds, in connection with the illumination by electricity of the Fine Arts Gallery which the Corporation is building.

Toynbee Hall.—The school and guild of handicraft, in connection with Toynbee Hall, Whitechapel, was formerly opened last Saturday afternoon by Sir W. Hart-Dyke, M.P., vice-president of the Council of Education. Some seventy pupils can already be accommodated, and the applications for admission far exceed this number.

Halifax and Bermuda.—In the House of Commons on Tuesday Mr. Raikes, in answer to Sir E. Watkin, said he had invited and received tenders for the laying of a cable between Halifax and Bermuda, and that they were now under the consideration of the Government. The work would be pushed forward as soon as the Government had come to a decision on the subject.

R.M.S. "Tartar."—This fine ship, of 4,339 tons burden, is lit throughout by electricity, an installation of 290 lights having been recently put in by Messrs. Siemens Brothers. There are duplicate sets of engines and dynamos, each capable of supplying 200 lights of 16 candle-power. The ss. "Tartar" is one of the Union Steamship Company's vessels which run between Southampton and the Cape.

Shackle Oil Insulators.—In the description of the oil shackle insulator of Mr. Higgins in our last issue, by an error due to the engraver the block was inserted upside down. The mistake was probably sufficiently apparent to mislead no one. We have since learnt that oil insulators of the shackle form have already been made by Messrs. Johnson and Phillips, to whom the introduction of this type of insulator is originally due.

Tory Island Lighthouses.—In the House of Commons on Tuesday, Sir M. H. Beach, replying to Sir E. Watkin, said he had reason to believe that Lloyd's were now in communication with the Postmaster-General on the question of taking further measures for the protection of life and property by connecting the improved lighthouses on Tory Island by electric cable with the mainland, and that there was a Bill on the subject now before Parliament.

South London Polytechnic Institutes.—A public appeal, signed by the Archbishop of Canterbury, Lord Ripon, Lord Rosebery, Lord Brassey, Dr. Lyon Playfair, Sir W. Hart-Dyke, and other influential persons, on behalf of the funds required to meet the liberal offer of the Charity Commissioners for the creation of technical institutes in South London. Donations may be paid to the chairman of the Executive Committee, E. Spicer, Esq., 50, Upper Thames-street, E.C., through the Bank of England.

Digitized by Google

Thunderstorms.—During the whole of the last fortnight scarcely a day has elapsed without the occurrence of thunderstorms of greater or less intensity in some parts of Great Britain, and in several cases loss of life and serious damage to property have been recorded. On Hampstead Heath two men who had taken shelter under a tree were struck by lightning, and one of them had his clothes partially torn off; both were severely injured. Storms of the same character are reported from many parts of Europe.

Transformer Litigation.—It is expected that the petition entered by Mr. Ferranti for the revocation of one of the Gaulard-Gibbs patents for secondary generators will come before the Courts to-day (Friday). In the original action, brought by Messrs. Gaulard and Gibbs against Sir Coutts Lindsay and Co. and Mr. Ferranti for infringement, the plaintiffs, having found it necessary to amend their pleadings, have decided in preference to abandon the action. We understand, however, that instructions have already been given to commence a new action against the same parties.

Edison's "Perfected" Phonograph.—*The Times* of Wednesday last contained an interesting letter from Colonel Gouraud, who has just received the first Edison phonograph of the new design which has reached this country. The instrument was accompanied by a set of phonograms giving a description of the invention in Edison's own voice, also an interesting selection of musical performances, &c. Although the phonograph is not an electrical instrument, it is yet so nearly related to the telephone that we feel sure that all our readers will watch its development with the greatest interest.

Alexandria.—Some further particulars have come to hand with regard to the scheme of M. Menasce for lighting Alexandria, Ramleh, and Helouan by electricity. In addition to the *concessionnaire* becoming responsible for all damage done to drains, gas pipes, and water pipes, which may be caused by running the leads underground, and having also to guarantee the Government against any legal proceedings which may be taken, the investigation committee advise that M. Menasce should deposit £10,000 as security. The concession is to be strictly personal, and is to confer no special privilege or monopoly. It is to last fifteen years, and lapses if the works are not begun by the 1st January, 1890. Finally, the *concessionnaire* is to pay the authorities an annual rental, based on the length of the mains. He may, however, if he chooses, in lieu of this tax, charge the authorities 50 per cent. less than the current price for all lights supplied to them.

The Chandler High-Speed Engine.—When the Chandler "Silent" high-speed engines were first introduced to notice by Mr. Bumsted, of Hednesford, some doubts were not unnaturally expressed as to the durability of single-acting, high-speed engines. The experience which has since been gained in ship lighting, particularly on board the British India Company's vessels, has, however, sufficiently demonstrated the perfectly reliable character of this type of engine. This satisfactory result is, no doubt, largely due to high-class workmanship, but it is also a consequence of the very perfect method of lubrication adopted. In addition to the greater simplicity of the single-acting engine, this type possesses also the advantage of running in almost absolute silence. We may add that the ss. "Taroba," the latest addition to the fleet of the British India Company, has been fitted with electric lighting plant by Messrs. W. Harrie and Co., of Glasgow, the dynamos being driven direct by a Chandler "silent" of 30 brake horse-power, running at the moderate speed of 400 revolutions per minute.

The Cost of Electrical Traction on Tramways.—The Fourth Avenue Street Car Company, which is one of the largest tramway companies in New York, has recently decided to adopt electric traction. This decision was only arrived at after an elaborate calculation as to the relative cost of traction by electricity, by horses, and by cable. The following table shows the results arrived at:—

	Electric.	Horse.	Cable.
Cost of cars	1	0·54	0·81
Motive power	1	1·45	1·06
Construction of roadway	1	0·53	2·09
Depreciation and repairs	1	1·47	2·04
Operating expenses (including wages)	1	3·38	1·71
Totals	5	7·37	7·74
Average	1	1·47	1·55

There are now at least sixty electric street tramways in the United States. The question is no longer concerning the success of the electric motor, but what kind of motor should be used—whether it shall be by continuous current or the storage batteries. The Fourth Avenue Company have selected the storage batteries and separate motors. A depot will be erected midway on the line of railway, where the batteries can be recharged when necessary. It is expected that one set of batteries will run for two consecutive trips.

The Barcelona Exhibition.—The *Diario de Barcelona* of 19th June, 1888, contains the following:—"The magic fountain, which attracts great attention in the Universal Exhibition, was seen for the first time in the Health Exhibition, South Kensington, London, in 1884. In the Inventions Exhibition in 1885, and in the Colonial of 1886, it appeared in much greater perfection than before, and was reproduced in Liverpool and at Staten Island, New York, in 1886, as also at the Glasgow Exhibition of the present year. The fountain of this city, however, considerably excels all the others. The motive power which is employed when all the jets of water and projectors of the electric light are at work is not under 300 horse-power. The constructors of the fountain are the Anglo-American Brush Electric Light Corporation, represented in Barcelona by Don José S. Noble, and the work has been under the management of Mr. William Bates, acting on behalf of the above-named firm. We must mention that the fountain was completed in a very short space of time, considering the great difficulties which had to be encountered in the course of erection. Mr. Raworth, the chief engineer of this English firm, has come out expressly to Barcelona for the official opening ceremony."

Summer Course of Lectures and Laboratory Instruction at the City and Guilds of London Institute.—We have pleasure in calling attention to the fact that a course of experimental lectures and special laboratory work on "The Construction, Testing and Use of Electrical Measuring Instruments" will be given in July next at the Central Institution, Exhibition-road, by Prof. W. E Ayrton, F.R.S. The lectures will comprise the principles and practice of the construction, calibration, and testing for faults of ammeters, voltmeters, ohmmeters, wattmeters, coulombmeters and ergmeters as used for direct and alternating current systems. The students' practical work will be conducted in a laboratory specially fitted with accumulators, standard instruments, &c., for electrical instrument testing, and they will have the opportunity of examining and practically trying all the more important electrical meters at present in ordinary use. The course will extend over two weeks, and will consist of six lectures, from 8 to 9 p.m., on Mondays, Wednesdays and Fridays in the fortnight com-

Digitized by Google

mencing on Monday, July 16th; and also of practical work in the physical laboratories, daily, Saturdays excepted, from 2 to 5 p.m., commencing on Tuesday, July 17th. The fee for the course, including laboratory instruction, is £2, and for the lectures only, 7s. 6d. Applications for admission should be received at the Central Institution, Exhibition-road, S.W., not later than July 6th.

Pierce v. the Liverpool Electric Supply Company (Limited). This was an action brought before the Chancery Court of the County Palatine of Lancaster, on June 14th and 19th, by Mr. Pierce, an emigration agent and hotel proprietor, against the Liverpool Electric Supply Company, of which Mr. Arthur Bromley-Holmes is managing-director, to restrain the company from working their engines at their central station in Tithebarne-street in such a manner as to annoy the plaintiff. It was contended on behalf of the plaintiff that the vibration caused by the machinery injured his business and the health of both his wife, sister, and himself. The company contended that for their own sake they ran the engines as far as possible without vibration, and stated that if the relative positions of the boilers and engines were so altered as to bring the former next the plaintiff's premises it would involve the stoppage of the light and an outlay of £900. The Vice-Chancellor, Sir H. F. Bristowe, when the evidence on both sides had been concluded, paid a personal visit to the premises of the plaintiff and of the company. Upon his return to the court his Honour said he thought it was rather a case for damages than for an injunction. The counsel on either side having agreed to this, his Honour assessed the damages to be paid to the plaintiff at £100, with costs. At the same time he stated that he had never seen better working machinery than that of the company.

Analogies of Heat and Electric Conductivity.—The analogies of heat and electric conductivity induced M. Bellati and S. Lussana to study the influence of light on the heat conductivity of selenium, the electric resistance of which, as is well known, is diminished on exposure. The plan of experiment consisted in sprinkling the double iodide of copper and mercury on the disc of selenium, on which a circular figure had been blackened with Indian ink. The selenium was heated by the passage of an electric current, which produced at first a dark spot, owing to the change in colour of the double iodide. This subsequently extended into a fairly regular circular figure, the measurement of the diameter of which afforded a means of determining the heat conductivity of the selenium. This method was found to be more practicable than the usual method of melting wax. In all cases, the diameter of the circle was greater when the selenium was exposed to reflected sunlight from which the greater part of the heat rays had been removed by passage through solutions of alum and of ammoniacal copper sulphate. The relation of heat conductivity without and with exposure to light was found to be in the ratio of 1:1·1 as the result of several concordant experiments. The same ratio was observed between the electric conductivities without and with exposure to light under conditions similar to those described above. The authors, however, would not insist on this concordance of results in the two phenomena.

Messrs. Lancaster and Tonge's Catalogue of Steam Traps, Pistons, &c.—Many of our readers will be already acquainted with the specialities manufactured by the firm of Lancaster and Tonge, engineers, of Pendleton, near Manchester, but if not, an examination of this catalogue will prove of considerable interest. The experience of over seven years has abundantly proved the value of the "Lancaster" steam trap, which consists of a loose disc valve at the orifice of the discharge pipe, in connection with a quick thread screw motion worked by the float. The special advantages of this form are found in its prompt action and entire freedom from sticking. The working parts are very simple, and are easily examined, and, in addition, no adjustment is required for varying pressures of steam. Another speciality of the same firm is the "Lancaster Serpent Coil Piston," in which the piston springs are made of tempered steel of circular cross-section, which renders it practically impossible for the piston to bind in the cylinder, and at the same time causes a revolving tendency in the packing rings. We select these two appliances as specially worthy of mention, because electrical engineers can afford to neglect nothing which promises to contribute to smoothness and certainty of action, and freedom from risk of breakdown in their steam plants. The catalogue describes various other appliances of interest, including vibration lubricators, adjustable pedestals, American unions, boiler fittings, high-speed governors, &c. The firm also manufacture engines of vertical, horizontal and diagonal types. At the Glasgow Exhibition their stand is No. 474, in the department of machinery in motion.

Royal Meteorological Society: Photographs of Lightning. The following circular has been issued by the Roya Meteorological Society:—"Sir: The Council of the Roya Meteorological Society are desirous of obtaining photographs of flashes of lightning, as they believe that a great deal of research on this subject can only be pursued by means of the camera. The council would esteem it a great favour if you, or the institution which you represent, could give them any assistance in this matter, either—1. By sending them copies of any photographs of flashes of lightning that may have already been taken. 2. By endeavouring to procure them yourself, or to interest others in so doing. It may perhaps be well to mention that the photography of lightning does not present any particular difficulties. If a rapid plate, and an ordinary rapid lens, with full aperture, be left uncovered for a short time at night during a thunderstorm, flashes of lightning will after development be found in some cases to have impressed themselves upon the plate. The only difficulty is the uncertainty whether any particular flash will happen to have been in the field of view. A rapid single lens is much more suitable than a rapid doublet, and it is believed that films on paper would effectually prevent reflection from the back. The focus should be that for a distant object, and, if possible, some point of landscape should be included to give the position of the horizon. If the latter is impossible, then the top of the picture should be distinctly marked. Any additional information as to the time, direction in which the camera was pointed, and the state of the weather, would be very desirable. The council hope, now that the thunderstorm season is approaching, many photographers, both amateurs and professionals, may be found willing to take up this interesting branch of their art. Last year a similar circular was issued by the society, and about 60 photographs of lightning flashes were received from various parts of Europe and America. These photographs have brought out several facts about lightning which had hitherto been entirely unsuspected. The committee of the society who are now investigating the subject feel that the amount of material at their disposal does not justify them in making any generalisations at present. They therefore earnestly appeal to you and others for further photographic evidence of the true nature of lightning flashes.—Yours, &c., WM. MARRIOTT, Assistant Secretary, 30, Great George-street, Westminster." [Some of the photographs alluded to above were reproduced in *The Electrician* of April 13th, 1888.]

UNIPOLAR INDUCTION.—IV.

BY G. W. DE TUNZELMANN, B.SC.

(Continued from page 204.)

In the last article, in referring to the experiments with the apparatus of Fig. 1, it should have been stated that the explanation that the lines of force are cut continuously by the disc applies only to the case in which the disc is made to revolve while the magnet remains fixed. When the magnet and disc revolve together, the fixed portion of the circuit is cut continuously by the lines of force, always in the same direction, and no lines of force cut the circuit in the opposite direction. The central portion of the magnet in Figs. 2 to 8 takes the place of the disc when the latter is rigidly connected to the magnet. This experiment is of considerable importance, owing to its having led Faraday to the conclusion that when a magnet rotates upon its axis the lines of force do not rotate with it.

As an E.M.F. was found to exist in the disc from the centre to the periphery, both when it revolved with the magnet, and when it revolved, while the magnet remained at rest, Faraday assumed that in each case the E.M.F. was due to the intersection of the lines of force of the magnet by the disc. On this assumption the experiment would show that the lines of force remained at rest, and Faraday's further conclusions from the whole series of experiments, that a magnet could receive opposite statical charges at its equatorial and polar portions respectively by rotation amongst its own lines of force would be justified. Having once taken up this point of view, Faraday would naturally suppose it to be confirmed by the result that no effect was produced when the magnet was made to rotate while the disc remained fixed. We have seen, however, that the results may also be explained on the assumption that the lines of force revolve with the magnet, only in this case the E.M.F. will not be due to an intersection of the lines of force by the disc when both magnet and disc revolve, but to the intersection of the fixed portion of the circuit by the revolving lines of force. These experiments, therefore, do not decide the question either way. Mr. S. Iolver Preston, in a Paper in the *Philosophical Magazine* of March, 1885, calls atention to this oversight on the part of Faraday of the possible explanation of the results by the intersection of the fixed circuit by the revolving lines of force.

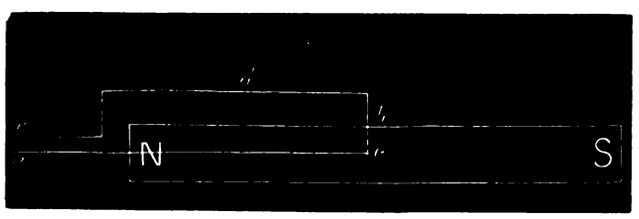

FIG. 13.

N S, magnet; *a e b d e*, loop of wire partly consisting of portion *a c* of axis of magnet.

One objection to Faraday's theory lies in its involving very complicated explanations of some of the experimental results obtained. Consider, for example, the experiment described in the first article with the apparatus shown in Fig. 8, according to which no current was obtained when the strip and the compound magnet rotated together. The arrangement is shown diagrammatically in Fig. 13. See Faraday's "Experimental Researches," No. 3,091.

N S is the magnet, *a*, *c*, *b*, *d*, *e* a loop, the portion *a c* of which consists of the axis of the magnet as far as its equatorial part *c*. The end *e* of the loop and the axis at *a* are connected with the terminals of the galvanometer. Faraday's explanation of the experimental result, that no current was obtained when the whole arrangement rotated about the axis of the magnet, was that the E.M.F. produced by the portion of the loop *b*, *d*, *e* intersecting the external lines of force, supposed to remain stationary, exactly balanced the E.M.F. produced by the portion *a c b* intersecting the lines of force in the interior of the magnet, and he considered ("Experimental Researches," No. 3,117) that this experiment proved that the lines of force are closed curves, so that there are the same number inside the magnet as outside. On the supposition which we have made, that the lines of force revolve with the magnet, the result follows at once as a result of there being no relative motion of the magnet and the circuit, and therefore no intersection of the lines of force by the circuit.

Plücker, in a Paper published in *Poggendorff's Annalen*, Vol. LXXXVII., 1852, described a number of experiments of the same general character as those made by Faraday, and he came to the same conclusion as Faraday, making the same oversight with regard to the effect which the revolving lines of force would have on the fixed portion of the circuit. He, too, was obliged to give very complicated explanations of many of the phenomena observed. For example, in one of his experiments he used six magnets fixed in a disc like the two magnets in the apparatus shown in Fig. 8 of the first article, the magnets being equidistant from each other and from the centre of the disc, and he accounted for the E.M.F. acting along the radius of the disc, which was produced by rotating the disc and magnets about the axis of the former, by supposing the field of force of each magnet to undergo a rotary displacement, without rotation, their motion being like that of a weight suspended by a ring from a peg which projects horizontally from the edge of a fly-wheel revolving in a vertical plane. He then supposed that currents were set up in the disc by the lines of force being made to intersect it in this manner.

A more fundamental objection to the view adopted by Faraday and Plücker consists in the fact that it involves an essential difference in the behaviour of the field of force of a magnet when the magnet undergoes a motion of translation and one of rotation respectively, as in the former case the magnetic field must necessarily move with the magnet. Faraday himself saw the difficulty, but believing that his

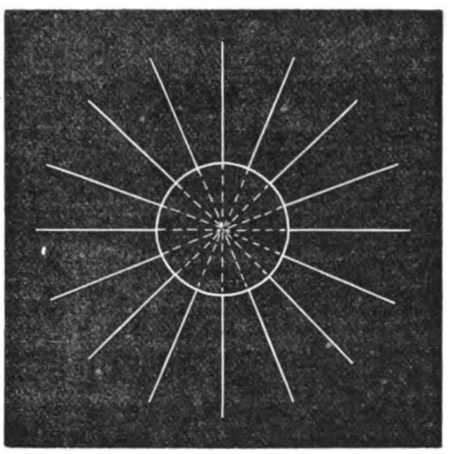

FIG. 14.

Section perpendicular to the axis of an infinite homogeneous circular cylinder, showing lines of force for gravitational attraction.

experimental results proved the field to be stationary when the motion of the magnet was one simply of rotation about its axis, he merely points out that the conclusion is singular. The inadmissiblity of making this distinction between the effect on the field, of motion of translation, and of rotation respectively, may, I think, be most easily seen by considering the simpler case of gravitation potential, where a line of force is the direction in which a small particle of matter tends to move in obedience to gravitational attraction.

Consider an infinite circular cylinder of homogeneous material, then the lines of force are straight lines, perpendicular to the surface, as shown in Fig. 14, which is a section perpendicular to the axis of the cylinder and its system of lines of force. The field of force will be exactly similar if the cylinder is a hollow one bounded by two concentric circular tubes. The field of force in either of these cases, like that of a cylindrical magnet, is not altered by rotation; the direction of the force at a given point in space will be the same whether we suppose the field to rotate with the cylinder or to remain stationary.

Digitized by Google

But consider now a thin, hollow cylinder formed by two tubes, every section perpendicular to the axis consisting of two concentric, similar and similarly situated ellipses. The equipotential surfaces will then consist of a series of elliptic cylinders, confocal with the outer surface of the hollow cylinder, so that the section perpendicular to the axis will give us the equipotential curves, a series of ellipses confocal with the outer section of the cylinder, and the lines of force, which must cut the equipotential curves at right angles, and will therefore consist of a series of hyperbolas confocal with the ellipses, as shown in Fig. 15. If the cylinder is now made to rotate about its axis, it is perfectly clear that the lines of force must

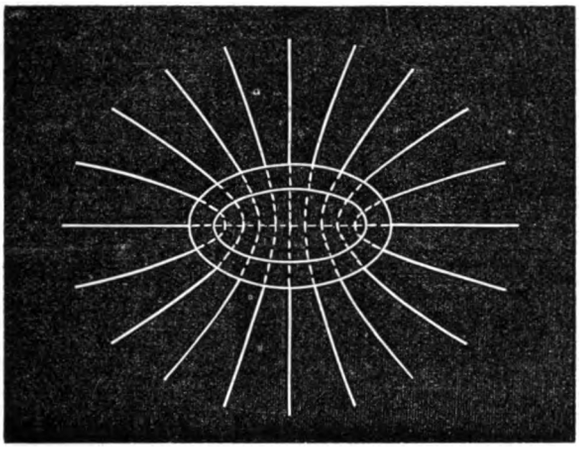

FIG. 15.

Section perpendicular to the axis of a homogeneous, thin, hollow cylinder, bounded by concentric, similar and similarly situated elliptic tubes, showing the hyperbolic lines of force for gravitational attraction confocal with the outer bounding ellipse of the section of the cylinder.

rotate with it. If the ellipses be made to approach a circular form the foci will approach the centre, and the system of hyperbolæ will approach more and more nearly to a set of straight lines passing through the centre, until in the limit, when the ellipses become circles, the field of force will be as shown

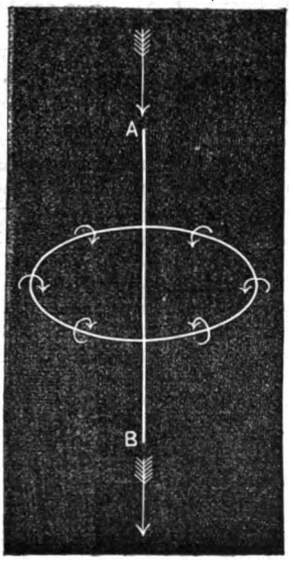

FIG. 16.

Straight current A B, showing one of its circular lines of force surrounded by electric whirls.

in Fig. 14. Now, however little the ellipses differ from circles, the field of force must be admitted to rotate with the cylinder when the latter turns about its axis, and it would be absurd to suppose a sudden change to take place in the limiting case when the field becomes symmetrical with regard to the axis. Similar considerations will evidently apply to magnetic lines of force, and we may therefore, I think, consider it proved that when a magnet rotates upon its axis, its lines of force rotate with it.

We now have to consider the physical meaning of this rotation of magnetic lines of force, and to do this we must try to form some conception of the nature of the action which goes on in a medium traversed by the lines. Ampère, as everyone knows, explained the actions of magnets on the assumption that every molecule of a magnet had an electric current circulating in it, which we may call an electric whirl. Sir William Thomson (*Proc.* Royal Society, June, 1856) expressed the opinion that the fact that the rate at which circularly polarised light is transmitted through magnetised glass, parallel to the lines of magnetic force, depends on whether the direction of transmission is the same or opposed to the positive direction of the lines of force, could only be explained by the existence of some kind of rotation in the medium. He therefore considered that Faraday's discovery of the magnetic rotation of the plane of polarisation of plane polarised light gave a confirmation amounting to demonstration of Ampère's explanation of the ultimate nature of magnetism. Two years later Helmholtz, in his famous memoir on vortex motion (*Crelle, Journal für Reine und Angewandte Mathematik*, Vol. LV., which was translated in the *Philosophical Magazine*, Vol. XXXIII, 4th Series, 1867), pointed out the analogy existing between an electro-magnetic field and a mass of fluid in which there is vortex motion. In 1861 and 1862 Clerk Maxwell published a series of papers in the *Philosophical Magazine*, in which he developed a theory of molecular vortices according to which lines of magnetic force were to be considered as forming the axis of electric whirls or vortices, as in Fig. 16, which shows a portion of a straight current, A B, with one of

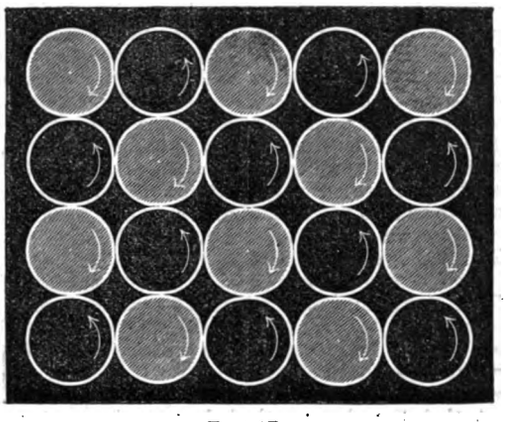

FIG. 17.

Maxwell's representation of a magnetic field.

its circular lines of force with the electric whirls round it. As two neighbouring whirls would be moving in opposite directions, he assumed that between every two of them was a particle turning in an opposite direction to the whirls and forming a connecting mechanism. Fig. 17 shows a magnetic field on this theory, the plain circles representing the electric whirls and the shaded circles representing the connecting particles. The directions of rotation are shown by the arrows. From this theory Maxwell deduced the following conclusions:—

(1) Magnetic force is the effect of the centrifugal force of the vortices.

(2) Electro-magnetic induction of currents is the effect of the forces called into play when the velocity of the vortices is changing.

(3) Electromotive force arises from the stress on the connecting mechanism.

(4) Electric displacement arises from the elastic yielding of the connecting mechanism.

On this hypothesis an electric current would be produced when a continuous slipping took place in the connecting mechanism, and we should have therefore to suppose that in a conductor continuous slip could take place, while in a dielectric there was no slip, but only an elastic yielding of the connecting mechanism.

This has been very well worked out, with some modifications, by Prof. Lodge in an admirable series of articles on

Digitized by Google

"Modern Views of Electricity," which have recently appeared in *Nature*. These papers are entirely non-mathematical, and are well worthy the attention of practical electricians.

Mr. R. T. Glazebrook, in a very interesting paper on the "Molecular Vortex Theory of Electromagnetic Action" (*Phil. Mag.*, 5th Series, Vol. XI., 1881), shows that if the moving medium be supposed to have the properties of a viscous fluid in conductors, and of an elastic solid in dielectrics, the additional particles, or idle whirls, become unnecessary, except as explaining how the vortices may be conceived to rotate.

If we adopt Maxwell's original theory or any of its modified forms, we have at once a physical explanation of the rotation of a magnet's lines of force, which will consist in the actual motion of the vortices through the medium surrounding the magnet. The electric currents which arise in a conductor traversed by the lines of force will therefore, on this theory, consist of motions of the medium within the conductor, due to the forces called into play as it is traversed by the series of vortices or vortex-filaments surrounding each line of force.

(To be continued.)

PROTECTION OF BUILDINGS FROM LIGHTNING.*

BY PROF. OLIVER LODGE, D.SC., F.R.S.

I made several assertions last week which it is my business now to justify by actual experiment.

The word "inertia" one uses as conveying a correct general notion of the behaviour of an electric circuit to sudden electromotive forces; a behaviour which is caused by the influence of induction which every portion of a circuit exerts on every other portion. Consider a conducting rod as analysed into a bundle of parallel wires or filaments, and let a current be suddenly started in all. The rising current in any one filament exerts an opposing force on all the others; and this self-generated opposition E.M.F., due to induction between the different filaments of the conductor, exactly imitates the effects of ordinary inertia as observed in massive bodies submitted to sudden mechanical forces. (For some illustrations of these well-known effects see a letter by Mr. Maclean, in *Nature*, Vol. XXXVII., p. 612.)

The term commonly employed to denote the electrical inertia-like effect is "self-induction," which is becoming gradually shortened to "inductance;" its original form when first dealt with by Sir Wm. Thomson was the "electromagnetic capacity" of the circuit.

Now since electrical inertia is due to a mutual action between the filaments into which a conductor may be supposed divided, it is manifest that the closer packed they are the greater their inertia will be; and that to diminish inertia it is only necessary to separate the filaments and spread them out.

The main count of the indictment against ordinary procedure is that too much attention has been hitherto paid to conducting power, and too little to inertia. In fact, it is not too much to say that practically nothing but conductivity has been attended to, or thought of, in the erection of lightning conductors.

I want to show that conductivity is, from many points of view, of hardly any moment, and that the circumstances of a discharge are regulated far more by inertia than by conductivity. I can even show that, under certain circumstances, high conductivity appears to be an actual objection, and that a stout rod of good conducting copper carries off a flash less well and quietly than a thin wire of badly-conducting iron.

Let us proceed to verify this paradoxical statement at once.

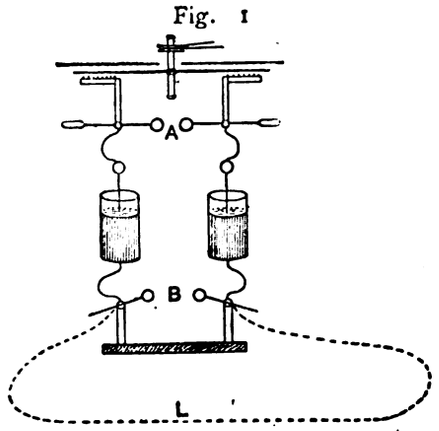
Experiment of the Alternative Path.

The first form of experiment I have to describe is a very simple one. I call it the experiment of the alternative path. It consists in giving a Leyden jar discharge the choice between a certain conductor and a certain length of air, and in adjusting the length of air until it had as lief take one path as the other.

I am not aware that the particular mode of carrying out this simple experiment has any special significance, but to be definite, I depict, in Fig. 1, the symmetrical arrangement I have most frequently, though not exclusively, adopted.

The knobs marked A are the ordinary terminals of a Voss machine. The jars stand on an ordinary wood table, and their outer coats are led to the discharger B, the distance of whose air-space can be varied. The alternative path L is shown by a dotted line. The discharge has to choose between B and L. Sometimes L is absent, and in that case the charging of the jars is quite well effected through the wood of the table; this is the advantage of having the jars imperfectly insulated. At the same time the conducting power of the wood is too low to enable the jars to discharge themselves at all satisfactorily, unless the knobs B are within striking distance, or unless some path, L, is provided. The only discharge obtained at A when both paths, B and L, are absent, is a feeble spitting or intermittent and frequent sparking, very different from the loud report heard as soon as the knobs B are brought within striking distance. But it is not to be supposed that the B knobs must be as close together as the A knobs in order to permit complete discharge; on the contrary, the B knobs may be almost twice as far apart as the A knobs, and yet the discharge shall be complete and noisy.

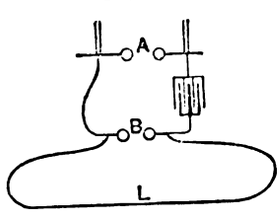
Fig. 1



It will be understood that the two sparks occur together; a spark at A precipitates, and is the cause of, the spark at B. Not *vice versâ*, for until the A spark occurs there is not the slightest tendency for a spark at B. The two B knobs are at the same zero potential, and may be touched with impunity except at the instant when the flash occurs at A. Remember that the jars are standing on a common table all the time.

Lest it be thought that there is anything occult in this mode of obtaining the spark at B, let us subjoin as Fig. 2 another arrangement of connection, which does just as well, and, in fact, represents the first experiment I tried. The condenser is a very large one of tinfoil and glass plates, with carefully insulated terminals. My object in making it was to obtain a sudden rush of a considerable quantity of electricity (like lightning), and then study its behaviour under various circumstances. I found afterwards that for most experiments an ordinary gallon or even pint Leyden jar served just as well, was much quicker in use, and less dangerous. Moreover, the use of insulated terminals necessitates the continued presence of some alternative path (L) or other, else of course the condenser declines to charge.

Fig. 2.



It may be noted at once that with either arrangement the spark A was very loud whenever the spark was allowed to occur at B as well; but so soon as the discharge was compelled to traverse the alternative conductor L, by putting the B knobs too far apart, then the noise of the discharge was much diminished, not merely because there is now only one spark instead of two, but plainly because, for some reason or other, the discharge meets with considerable obstruction in the wire, whereby its duration is lengthened, and its noise therefore very greatly lessened.

The numbers given below are extracted from a page of the laboratory note-book, and refer to an experiment with two Leyden jars, of a size which I sufficiently specify by calling them "gallon" jars, arranged as in Fig. 1. The length of the A spark was maintained at one inch throughout the experiment; or as it happened to be accidentally convenient to measure lengths in tenths of an inch, I will call the A length 10. The B length is variable, being altered until a B spark sometimes passes and sometimes misses.

* Lecture II. of the Dr. Mann lectures, delivered before the Society of Arts, March 17th, 1888.

Digitized by Google

The first alternative path I show is a length of about 40ft. of stout No. 1. (B.W.G.) copper wire or rod, suspended round the room by silk ribbon. Its resistance to ordinary currents is very small, being ·025 ohm. Nevertheless, we shall find that the discharge refuses to take this apparently easy path, and persists in jumping the air gap B instead, until the B knobs are separated 14·3 tenths of an inch. This is the critical distance. If they are further apart than this the discharge chooses the thick copper wire by preference, and its noise or suddenness is then much less.

As a contrast with this, I next try a similar length of fine iron wire (No. 27, B.W.G.), whose resistance to ordinary currents is 33·3 ohms, or 1,300 times as great as the other. We find that the discharge very distinctly prefers this wire to the other. For if the B knobs remain at the distance 14·3 we never now get a B spark, nor do we get one until they have been brought distinctly nearer. The critical spark length is now 10·3. I confess I was surprised at this result.

Let us next try an enormous resistance—a capillary tube of liquid (very dilute acid), giving to ordinary measurements some 300,000 ohms. The critical spark length at B is, indeed, a little increased by this great resistance, but not much above that found for the stout copper wire. I have not an exact measure of it, but 16 or 17 will not be far out. The spark at A now becomes very quiet indeed, pointing to the fact that what we were observing all along was, in some sense or other, the effect of true resistance; for the undeniable resistance in the capillary tube gives just the same kind of effects as does the copper or iron wire, only a little more pronounced.

I have suspended three other conductors of about the same length, which it is easy to try in the same way, keeping the A spark-length 10 all the time. The results are here summarised :—

Alternative Path.		Critical B spark-length.
Stout copper wire, No. 1	R= ·025 ohm	14·3
Ordinary copper wire, No. 19	R= 2·72 ,, ...	13·4
Stout iron wire, No. 1	R= ·086 ,, ...	10·8
Ordinary iron wire, No. 18	R= 3·55 ,, ...	10·8
Thinnest iron wire, No. 27	R=33·3 ,, ...	10·3

The copper wires seem to obstruct almost equally, and the iron wires also obstruct equally among themselves, notwithstanding their very different diameters; but the coppers obstruct more than the irons.

There is nothing absolute about these numbers; they are the record of a definite experiment, but their precise value depends on the circumstances of the experiment. It is easy to arrange it so that the iron is less effective than the copper—so that, in fact, ordinary resistance seems to become of consequence again. This is done by putting a long lead into the A circuit of the jars. But whenever the flash is made as sudden as possible—and there seems little doubt but that a lightning flash is very sudden—then the order of the numbers is something like the figures quoted.

Reason of the Enormous Obstruction Offered by a Good Conductor.

Now, what is the cause of all this astonishing obstruction offered by good conductors to the sudden rush of electricity? One may express it in a popular way, thus :—It is due to electrical inertia, or what is also called "self-induction." A current cannot start in an inductor instantaneously any more than water in a pipe can start moving at full speed in an instant. Give the water a violent blow to make it move, and it resists like a solid. The blow, if very quick and violent, may burst the pipe, but it will not appreciably propel the water. So, in a manner, is it with electricity. The flash occurs, and the conductor must either carry it off at once or not at all. There is no time to think about it, and the E.M.F. needed to overcome this inertia-like obstruction is so great that a considerable thickness of air may be burst by it, and the discharge may flash off sideways to anything handy.

Another way of putting the matter is this :—A lightning discharge is essentially a varying current; it manifestly rises from zero to a maximum, and then dies away again, all in some extremely small fraction of a second, say 100,000th, or thereabouts. But that is not all; there is a certain amount of energy to be got rid of, to be dissipated, and it may easily be that a single rush of electricity in one direction does not suffice to dissipate all the stored-up energy of the charged cloud. If the conductor is highly resisting, a single rush is sufficient, but if it be well-conducting it is quite insufficient. What happens then? The same as would happen with compressed air or other fluid rushing out of an orifice. If it is a narrow jet there is a one-directioned blast, but if a wide, free mouth be suddenly opened the escaping air overshoots itself by reason of inertia, and springs back again, oscillating to and fro till the stored-up energy is dissipated. Just so is it with an electric discharge through good conductors; it is not a mere one-directioned rush, it is an oscillation, a surging of electricity to and fro, until all the energy is turned into heat.

This fact is often forgotten by lightning-rod men; they speak as if there were a certain quantity of electricity to be conveyed to earth and there was an end of it, but they forget the energy of the electric charge, which must be got rid of somehow. If a great weight or a large reservoir of water were propped up above one's house, one would not say that, the safe thing being to get it down as quickly as possible, it was advisable to knock the props away or to blow the bottom out of the reservoir; no, one would prefer to let it slide slowly and gradually down a well-resisting channel, so as to disperse the energy gradually.

We will remember, then, that a Leyden jar discharge through good conductors is oscillatory, and that the oscillation continues until all the stored energy is rubbed away. The oscillations have an enormous frequency; they may be millions a second, for the whole lot of them have to cease during the excessively minute duration of the visible flash. It is well known that a flash is of far less real duration than the persistence of optical impression on the retina would lead one to believe; as is easily illustrated by illuminating a spinning wheel by an electric spark. However fast (ordinarily speaking) the wheel is spinning it appears to be stationary, and the spokes are seen singly and clearly by the light of each spark.

It is for this reason that, although the illuminating power of a powerful flash need not be greater than weak moonlight, its actual intensity while it lasts may exceed strong sunlight, and hence may exert a damaging effect on the retina, and cause blindness.

There is another fact which it behoves us to be aware of. It is one to the importance of which the attention of scientific men has but recently been called. Experimentally it has been discovered by Prof. Hughes, theoretically by Mr. Oliver Heaviside, Lord Rayleigh, and Prof. Poynting; for though the necessary theory is really contained in Clerk Maxwell, it required digging out and displaying. This has now been abundantly done, but the knowledge has scarcely yet penetrated to practical men; indeed, it has not yet been thoroughly assimilated by most physicists. The fact is this. When a current starts in a conductor, it does not start equally all through its section, it begins on the outside, and then gradually, though rapidly, penetrates to the interior. A steady current flows uniformly through the whole section of a conductor, a variable current does not. It is started first at the surface, and it is stopped first at the surface.

Remembering the rapidly oscillating character of an electric discharge, remembering also the fact that a rising current begins on the outside surface of a conductor, we perceive that, with a certain rate of alternation, no current will be able to penetrate below the most superficial layer or outer skin of the conductor at all. In the outer skin, of microscopic thickness, electricity will be oscillating to and fro, but the interior of the conductor will remain stolidly inert and take no part in the action.

Thus we arrive at a curious kind of resistance, caused by inertia in a roundabout fashion, and yet a real resistance, a reduction in the conducting substance of a rod, so that no portion except that close to the surface can take any part in the conduction of these rapidly alternating currents or discharges. It must naturally be better, therefore, not to make a lightning conductor of solid rod, but to flatten it out into a thin sheet, or cut it into detached wires; any plan for increasing surface, and spreading it out laterally will be an improvement.

Perhaps it may be as well to guard against one favourite misconception. It has long been known that static charges exist only on the surface of conductors; it has also long been known that ordinary currents flow through the whole section and substance of their conductors. It is now beginning to be known that alternating currents may be sufficiently rapid to traverse only the outer layers of conductors, and this last piece of knowledge is felt to be rather disturbing by those who have been accustomed to dwell upon the behaviour of steady currents, and seems like a return to electrostatic notions, and an attempt to lord it over currents by their help. But the first and third facts mentioned above—the behaviour of static charges, and the behaviour of alternating currents—are two distinct facts, independent of each other; not rigorously independent perhaps, but best considered so for ordinary purposes of explanation.

We have thus mentioned two causes of obstruction met with by rapidly oscillating currents trying to traverse a metal rod. First there is the direct inertia-like effect of self-induction to be added to the resistance proper; the resulting quantity being called by Mr. Heaviside "impedance," to distinguish it from resistance proper. For there is a very clear distinction between them; resistance proper dissipates the energy of a current into heat, according to Joule's law; impedance obstructs the current, but does not dissipate energy. Impedance causes tendency to side flash, resistance causes a conductor to heat and perhaps to melt. The greater the resistance of a conductor, the more quickly will the energy of a discharge be dissipated, its oscillations being rapidly damped; the greater the impedance of a conductor, the less able is it to carry off a flash, and neighbouring semi-conductors are accordingly exposed to the more

Digitized by Google

danger. Resistance is analogous to friction in machinery; impedance is analogous to freely suspended massive obstruction, in addition to whatever friction there may be. To slowly changing forces friction is practically the sole obstruction; to rapidly alternating forces inertia may constitute by far the greater part of the total obstruction; so much the greater part that friction need hardly matter.

This is a fairly accurate popular statement of the direct way in which self-induction aids the resistance proper in obstructing an alternating current. But, in addition to these considerations, there is that other indirect way which we have also mentioned, viz., the fact that conduction of alternating current may be confined to the surface of a rod or wire if the alternations are rapid enough. This cause must plainly increase total impedance; for the total channel open to such a current is virtually throttled, as a water pipe would be throttled by a central solid core.

But which part of the total impedance does it affect? Does it increase the resistance part or the inertia part? In other words, does this throttling of a conductor act by dissipation of energy or by mere massive sluggishness? Plainly, it must act like any other reduction of section, it must increase the resistance, the dissipating power of a conductor, the heating power of a current. Hence the resistance of which we have spoken as entering into the total impedance has by no means the same value as it has for steady currents, and as measured by a Wheatstone bridge. It is a quantity greater—possibly much greater—than this; and in order to calculate its value, we must know not only the sectional area and specific conductivity of the conductor, but also the shape of its section, and the rate of alternation of the current to be conveyed.

Tape *v.* Rod.

We may here note a vigorous controversy, or difference of opinion, between Faraday on the one hand, and Sir W. Snow Harris on the other. Faraday was often consulted about lightning conductors for lighthouses, and consistently maintained that sectional area was the one thing necessary, weight per linear foot, and the shape was wholly indifferent. Harris, on the contrary, maintained that tube conductors were just as good as solid rods, and that flattened ribbon was better still. Each is reported to have said that the other know nothing at all about the matter. Of course we know that Faraday was thinking of nothing but conduction, and conduction for steady currents. Harris had probably no theoretical reason to give, but was guided by either instinct or by the result of experience. I think we shall have to admit that, in this particular, Faraday was wrong and Harris was right. The following experiment may serve to illustrate the point further:—

I take two copper conductors of the same length and approximately of the same weight, but one of them in the form of wire, the other in the form of ribbon, and I use them successively as an alternative path. The knobs at A being fixed at two centimetres apart, the B knobs were adjusted until the spark sometimes chose the air gap, and sometimes the alternative conductor. (*See* Fig. 1 or 2.) The critical B spark length was then:—

	Millimetres.
With the wire as alternative path.....	8·36
With the ribbon ,, ,, ...	6·26
,, wire ,, ,, ...	8·45
,, ribbon ,, ,, ...	6·05
,, wire ,, ,, ...	8 21
,, ribbon ,, ,, ...	6·06

Very distinctly showing the advantage of a flattened form of conductor over a mere round section.

The dimensions of the two conductors here compared are as follows:—Wire: No. 12 B.W.G., 218 centimetres long, weight 91·6 grammes. Ribbon: 218 centimetres long and 6·4 centimetres broad, weight 88·7 grammes.

But, it may be said, have not experiments often been made as to the advantage of tape over rod forms of lightning conductor, with negative results? Yes, but the point usually attended to is the deflagration of the conductor. Mr. Preece, for instance, with Dr. De la Rue's battery, found ribbon and wire equally easy to deflagrate by the discharge. But we are not examining which form of conductor is least liable to be destroyed by a flash—probably there is not much to choose between one form of section and another, for there is no time for surface cooling—we are examining which form will carry off a charge most easily, and with least liability to side-flash; and here thin ribbon shows distinct advantage over round rod.

Iron *v.* Copper.

You remember we have found that a rod of iron carries off a discharge more satisfactorily than a rod of copper. It would seem as if the poorer conducting qualities of iron enabled the discharge to penetrate deeper, and so to make use of a greater thickness of skin.

But everyone will say—and I should have said before trying—surely iron has far more self-induction than copper. A current going through iron has to magnetise it in concentric cylinders, and this takes time. But experiment declares against this view for the case of Leyden jar discharges. Iron is experimentally better than copper. It would seem, then, that the flash is too quick to magnetise the iron; or else the current confines itself so entirely to the outer skin that there is nothing to magnetise. A tubular current would magnetise nothing inside it. Somehow or other the peculiar properties of iron, due to its great magnetic permeability, disappear.

I do not believe anyone could have expected this result. Possibly Lord Rayleigh might have predicted it, and perhaps Mr. Oliver Heaviside. It would scarcely become me to express admiration for the work of so great a master of science as Lord Rayleigh (though, parenthetically, I may mention that I feel such admiration in the highest degree), but I must take the opportunity to remark what a singular insight into the intricacies of the subject, and what a masterly grasp of a most difficult theory, are to be found among the eccentric, and in some respects repellant, writings of Mr. Oliver Heaviside. I cannot pretend to have done more than skim these writings, however, for I find Lord Rayleigh's papers, in so far as they cover the same ground, so much pleasanter and easier to read; though, indeed, they are none of the easiest.

Can this suggestion with regard to iron be examined and verified or disproved in some other more direct way?

It is easy to try another experiment. I have here two conductors made of tinfoil; each is made of a long slip of tinfoil, about three inches broad and 21ft. long. One is zigzagged backwards and forwards, with the interposition of three thicknesses of paraffin paper between each zigzag to secure insulation, so as to abolish self-induction as far as possible. This I call the tinfoil zigzag. The other is coiled spirally on a glass tube—again with the interposition of paraffin paper—so as to give as much self-induction as possible. This I call the tinfoil spiral. A bundle of fine iron wires—the core of an induction coil, in fact—can be introduced into this glass tube, or withdrawn, at pleasure. The resistances of these conductors, measured in the ordinary way, are:—·614 ohm for the spiral and ·708 ohm for the zigzag. They were intended to be alike.

The connections being made as in Fig. 1, one or other of these tinfoil conductors is used as the alternative path L, with this result:—

The length of the A spark being 7·3, the critical spark length at B, when sparks sometimes passed and sometimes failed, was 11·1 when no alternative path was provided. When the tinfoil zigzag connected the outsides of the jars instead of the wire L it was not possible to get a B spark till the distance was shortened to 0·6; when this was replaced by the tinfoil spiral, the critical B spark length rose to 6·4. The iron bundle was now inserted in the spiral, and the experiment tried again. The B spark length remained 6·4. The iron made no perceptible difference whatever.

Here is a magnetic time-lag raised to an extreme. Prof. Ayrton tells me they have noticed the permeability of iron begin to diminish with very quick alternations. Here it is becoming virtually no bigger than that of air. It may be said that the iron fails to get magnetised because of the opposing action of the inverse "Foucault" currents induced in it, just half a period behind the inducing currents. I thought this would be so, of course, with thick rods of iron, but with a bundle of thin wires I felt doubtful. Lord Rayleigh, however, thinks these induced peripheral currents competent to explain magnetic time-lag in every case; and I can have no doubt that he is right. Whatever the explanation, the fact of time-lag in iron is patent. Yet there is something strange about it, for that a steel knitting needle can be magnetised by discharging a Leyden jar round it is mentioned in every text-book, and (what does not necessarily follow) it is certainly true. There are points here requiring further examination.

However, if it turns out to be true that an iron rod does not get magnetised by the passage of a rapidly alternating current, it may be held a natural consequence of the fact that such currents flow mainly in its outer surface, and that such tubular currents have no magnetising power on anything inside them.

The magnetisability of iron is no objection to its employment in lightning conductors. Its inferior conductivity is an advantage in rendering the flash slower, and therefore less explosive. Its high melting point and cheapness are obvious advantages. It is almost as permanent as copper, at least when galvanised, and it is not likely to be stolen. I regard the use of copper for lightning conductors as doomed.

(To be continued.)

The Telephone in Hungary.—A Bill has just been laid before the Hungarian Chamber relating to telephone lines. Concessions lasting fifty years are to be granted, and the Bill contains elaborate instructions on various points connected with the general uses of electricity.

ALTERNATE-CURRENT ELECTROLYSIS.*

When the current from an alternate-current dynamo is passed through an ordinary voltameter containing platinum electrodes and acidulated water, no evolution of gas is, as a general rule, observed. There seems, in fact, to be no decomposition of the dilute sulphuric acid, although the circuit is closed. For instance, with currents of 4 to 5 amperes and an E.M.F. of from 250 to 300 volts, no trace of gas is found at the electrodes, provided that the platinum rods exceed ·1 centimetre in diameter and 4 to 5 centimetres in length. Hence arises the common notion that alternate currents are as incapable of splitting up the liquid in a voltameter as they are of deflecting the needle of a galvanometer. This idea is erroneous. It is only an apparent inability to electrolyse, since, if we substitute fine wires for the larger electrodes in the very same voltameter, the same alternate-currents will immediately liberate gas freely.

The experimental study† of this phenomenon has led us to form the following conclusions :—1. For every current there is a platinum electrode whose surface is such that gas is not evolved, and electrolysis actually is, or seems to be, completely checked. If now we gradually reduce the surface of the electrode, gas is liberated more and more as the area of the electrodes is diminished. 2. Conversely for every platinum electrode of a certain size there is a current below which there is no evolution of gas. On the other hand, more and more gas is evolved as the current strength is increased. 3. In every case chemical analysis has shown that the gases at either electrode have the same composition. They are, in fact, the gases of water, forming an explosive mixture, but in which oxygen forms less than a third of the total volume. Moreover, the volume of gas liberated per ampere-minute is always more or less under the theoretical quantity of 10 4cc., which would under similar conditions be evolved by a continuous current.

One of the most interesting phenomena of this electrolysis is the fact that we have ozone liberated at each electrode, notwithstanding the presence of hydrogen. If the gases are allowed to evolve freely in the open ozone is soon detected by its strong smell and even by the characteristic white fumes. We were easily able to measure it, and found that its proportions, at the same temperature, depend chiefly upon the current density and the nature of the electrodes and electrolyte. At present, however, we will speak only of the fact of its production, which plays an important part in the correct interpretation of these phenomena.

It seems natural to us that, given a simultaneous evolution of highly ozonised oxygen, and of nascent hydrogen upon the same electrode, the slightest external action should be quite sufficient to cause the re-formation of water and the consequent disappearance of the gases. Now, in the case of platinum electrodes an external cause is present in the property of occlusion possessed by this metal, which is proportional to the metallic surface in contact with the gases. We have here, therefore, a plausible explanation of the phenomena. This view is confirmed by several of our experiments, of which we will only now cite two.

1. Copper electrodes do not decompose acidulated water under the same conditions of current density as do platinum electrodes. Nevertheless, they become coated with a film of reduced red copper. If finer wires are used there is an abundant liberation of gas, which, however, does not last long, as the electrodes soon dissolve, so to speak, in the liquid in streaks of powdery reduced red copper. The copper is thus first oxydised by ozonised oxygen, then it is reduced by the hydrogen with recomposition of water. It is easy to see that if the surface is only large enough, not a single bubble of gas can be evolved. We have here, therefore, re-absorption of the gases caused by a double chemical reaction.

2. With large mercury electrodes a slight quantity of gas is liberated, and from time to time a cloud of white matter is produced, which slowly spreads over the whole voltameter. This gas is formed almost entirely of hydrogen. The solid is a sulphate of mercury (a salt which is hardly soluble). It is known that a continuous current would only produce sulphate-protoxide. Here again, therefore, we have re-composition of water at the expense of the gases which might otherwise have been liberated. The cause must be sought for both in the absorptive properties of mercury and in the double reaction which the metal and sulphate-protoxide undergo.

These secondary reactions explain also the difference between the volume of the gases liberated for a given strength of alternate-current and the theoretical volume deduced from Faraday's law. Nevertheless, we shall show in a later communication that by a proper choice of electrolyte and electrodes results may be directly or indirectly obtained which will be strictly proportional to the total quantity of electricity traversing the electrolyte. We shall then have an electrolytic means of measuring alternate-currents. These two experiments prove, moreover, how very much the primary and secondary reactions of alternate-current electrolysis differ from the ordinary electrolytic reactions caused by continuous currents. We have noticed several other instances of this. We think it our duty to add that the evolution of this explosive mixture renders these investigations rather delicate, not to say dangerous. There is always a chance of a spontaneous explosion, unless certain precautions, which we will mention in our next Paper, are taken.

The Electrician.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial and Publishing Offices
No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.
Telephone No. 2714.

All Communications to be addressed to "THE ELECTRICIAN," *1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* THE PROPRIETORS.

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained at all Booksellers and Newsvendors; or direct from the office as above.*

SPECIAL NOTICE.

Owing to the increase in the number of pages of "THE ELECTRICIAN," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months.
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	... 12 6	... 24 0
„ Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	... 14 6	... 28 0
The rates for the United Kingdom remain as follows:—	4 11	... 9 9	... 19 6

"The Electrician" in America.

"THE ELECTRICIAN" *can be obtained in America from* D. VAN NOSTRAND, *23, Murray-street, and 27, Warren-street, New York.*

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to this office.

Advertisements intended for the current issue must be handed in not later than 4 p.m. on Thursday.

TECHNICAL PRINTING.

THE PROPRIETORS *of* "THE ELECTRICIAN" *beg to inform Electricians and Electric Light Engineers that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

The Electricians' Directory.

Royal 8vo. Cloth Boards, 3s. 6d. Boards, 3s.

At the end of December in each year is issued THE ELECTRICIANS' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and has now attained considerable proportions. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, accompanied in many cases by Portraits.*

THE DIRECTORY FOR 1888 IS NOW READY.

SPECIAL NOTICE.

We shall be glad if those of our readers who obtain copies of the "ELECTRICIAN" through newsvendors will bring to our notice any case in which leaflet advertisements of an objectionable character are inserted in the paper. No advertisement leaflets of any kind are ever inserted at this office, and newsvendors inserting such leaflets render themselves liable to prosecution.

ANSWER TO CORRESPONDENT.

PERCY W. LONG.—(1) *In the company you name promotion is slow, but the rate of payment depends in part on the skill attained. Cannot say what the salaries are.* (2) *The profession is undoubtedly overcrowded at the present time, but really clever men have still a chance of coming to the front.*

TELEPHONIC COMMUNICATION.

No one can be surprised that the United Telephone Company have decided to drop for the present Session their Bill seeking further powers in respect to the erection of overhead wires and other matters affecting the future development of telephonic business in the metropolitan area. It seems to have been generally admitted that the company were asking for more than they were at all likely to get, and if any doubt on this point remained in the minds of the promoters it was speedily disposed of by the action of the metropolitan parliamentary representatives, who let it be known that they intended to offer the Bill a somewhat uncompromising opposition. Added to this there were the several recent utterances of the POSTMASTER-GENERAL, indicating with more and more distinctness every time he referred to the subject that he was not disposed to concede to the telephone companies greater powers of extension than they already possessed. The Bill promoted by the parent company closely concerned all the subsidiary companies as well, for it would have been impossible to refuse to the provinces any privileges which the metropolis had obtained for itself; and thus there was a widespread desire to know precisely what Mr. RAIKES intended to do when the United Company's Bill came on for discussion, as it was expected to do in the present week. The deputation which waited on him last week was therefore a representative one; and the practical suggestion it had to offer in face of a formidable opposition in Parliament was that the Bill should be referred to a Select Committee. This the POSTMASTER-GENERAL flatly declined to countenance, and the upshot was that the deputation came to the unanimous conclusion that it would be better not to press the Bill any further.

Digitized by Google

Besides the reasons above mentioned for taking this sensible course, there was no doubt another and perhaps even more cogent one. The published accounts of the interview are very meagre indeed; but it seems pretty clear that Mr. RAIKES repeated the declaration which created such a sensation a few weeks ago with reference to the moribund condition of the telephonic patents. To tell the public that the patents have only a few years to run, and that he will then see what can be done, was a piece of candour as uncalled for as it was unprecedented; but to say the same thing to the patentees themselves, as some accounts say he did last Friday, was frankness which may fairly be called brutal. No wonder the deputation retired disconcerted; and no wonder that the organs which profess to safeguard the interests of telephonic shareholders are furious with the present POSTMASTER-GENERAL for taking what they consider an unfair advantage of the company's position. We cannot pretend to sympathise with the financial organs in this particular, for they have done their very utmost to discredit the United Telephone Company by constant attacks upon its management and personal reflections upon its managers. The *Financial News*, at all events, has no need to be astonished that the Post Office does not adopt a superfinely magnanimous view of its duty towards the principal telephone company. If half of what has been said in that journal hostile to the company were true, Mr. RAIKES would be more than justified in taking sides against it on behalf of what he conceives to be the public welfare. But we do not share the opinions of these financial critics; and on the whole we think the telephone companies have been hardly treated in not having been apprised earlier of the policy the Post Office intended to pursue in regard to them.

In the first place the original agreements entered into with Mr. FAWCETT were for such a long period of years as to exclude the supposition that the strict legal rights of the Government would be enforced at a much earlier date when the patents expired. Secondly, the action of the Post Office ever since those agreements were signed has pointed rather to a gradual abandonment of its pretensions. Telephonic exchanges which the Post Office had then opened, or subsequently organised, have not been pushed forward; in many cases they have been allowed to languish, and in others have been abandoned altogether. We are unable to detect any sinister design in this apparently deliberate course of inaction; and it has certainly been interpreted as meaning that the private telephone companies were being left in undisturbed possession of the field not merely for a few years but for all time. The supposition was perhaps unreasonable; but we are speaking of facts, and one fact comes out conspicuously in the present discussion, namely, that the companies and their organs in the press have utterly forgotten that the agreements with the Post Office were terminable, and rested mainly on its grace and good pleasure at the end of a short term of years.

There is one passage, however, in Mr. RAIKES' speech which, if he is correctly reported, may be taken as a crumb of comfort to every one of the telephone companies, provincial and metropolitan alike. Next year this vexed question of telephonic extension by means of overhead wires may, to some extent, be relegated to the County Councils created under the Local Government Bill, if it passes this Session. With these County Councils the respective companies would then have to deal, and it will be their own fault if they do not succeed in obtaining any concessions they can reasonably demand. Meanwhile they should take care not to handicap themselves with a heavy weight of popular prejudice, as the metropolitan company has unfortunately done. On the part of the companies it may be fairly urged that the telephone cannot dispense with overhead wires, whether worked by private enterprise or by the Government. Although the Post Office in London has placed nearly the whole of its vast network of wires underground, its officials gave evidence before the Select Committee last year to the effect that overhead wires were not only perfectly safe but absolutely necessary. The question is partly one of expediency, partly of ultimate economy; there is at present very little danger of its becoming one of necessity. Nobody proposes to compel the removal of all house-top and over-street wires; and we do not suppose that the local councils will adopt any such policy. Some fresh powers, however, are needed by the companies, if only to prevent the very dangers and offences which they are sometimes charged with gratuitously occasioning. It is not to be expected that the Post Office will be content that private companies should obtain powers which the State Telegraphs do not possess; but, on the other hand, it may be hoped that any powers with which the telephone companies can be safely entrusted will not be withheld by local bodies, or vetoed by the POSTMASTER-GENERAL. According to our information, he expressed no intention of handing this matter over to the County Councils. Be that as it may, the POSTMASTER-GENERAL will have to be reckoned with in any case; and the way he has frustrated the United Telephone Company in London ought to be a lesson to its subsidiary companies in the provinces. The reflection may not be pleasant, but it is needed all the same.

GLASGOW INTERNATIONAL EXHIBITION.

The Glasgow International Exhibition of Industry, Science and Art was opened on the 8th of May by the Prince of Wales, and up to the present has been very successful in attracting a large attendance of visitors, over one million having passed the turnstiles during the first five weeks.

The electrical exhibits at this Exhibition are neither so numerous nor so important as might have been expected. Few of the leading firms of electrical engineers appear at all in the list of exhibitors, and those that do are nearly all in some way or other connected with the lighting of the buildings and grounds. Taken as a whole, the exhibits do not show the advance on those of previous Exhibitions that the progress made during the last year or two might have led us to expect. There is no installation on the transformer system shown, and no plant of any magnitude illustrating this very important factor in modern electric lighting practice. One or two specimens of alternate-current transformers are exhibited by Kennedy, of the Woodside Electric Works, Glasgow, and a transformer is being used in connection with an exhibit of electric welding shown by the Thomson-Houston Company. There are a few good exhibits of combined engines and dynamos suitable for ship and other lighting, and of electrical instruments and other appliances, among which may be mentioned those of Anderson and Munro, Glasgow; the Anglo-American Brush Corporation, London; Clark, Muirhead and Co., Westminster; The Edison-Bell Telephone Company, Glasgow; Greenwood and Batley, Leeds; Harvie and Co., Glasgow; The India Rubber and Telegraph Company, Silvertown; Rankin Kennedy, Glasgow; King, Brown and Co., Edinburgh; Millar and Co., Glasgow; Richard Miller, Glasgow; F. J. Rowan, Glasgow; and a few others. We hope to refer more particularly to some of these in future articles.

As was to be expected, electricity plays an important part in the lighting of the buildings and the grounds of the Exhibition. The interior of the main building is, with the exception of a small section of the machinery court, entirely lighted by arc and incandescent lamps. In the part of the machinery court which forms the exception just referred to, there is an excellent display of regenerative gas lamps. These lamps are of three types, namely, the Wenham, the Bower, and the Siemens flat flame lamps. The Wenham exhibit consists of

Digitized by Google

sixteen lamps, the Bower of nineteen, and the Siemens of thirty lamps. These exhibits form excellent examples of what can be done by gas, and are good illustrations of the impetus which the electric light has given to that industry. There are several other examples of gas lighting, and also of one of the most modern systems of oil lighting, to be seen in buildings situated in the grounds. For example, there are thirty-nine Wenham lamps in use in the Royal Bungalow dining rooms, twenty Thomas lamps in the Bachelors' Café, while in two kiosks, one occupied as chocolate rooms and the other as smoking rooms, there are good exhibits of the Welsbach system of incandescent gas lighting. Defries' safety oil lamps are used in a large *café* occupied by Messrs. Lyons and Co., and in several tea rooms and lavatories. It will thus be seen that although the largest share of the lighting has been given to electricity, yet it has by no means got a monopoly, but is placed side by side with some of its most important rivals.

The arc lighting contracts have been secured by the Anglo-American Brush Company, and by Mr. Richard Miller, agent for the Thomson-Houston Company. The Brush installation includes the lighting of the whole of the grounds and all the electric lighting inside the main building, except the first-class refreshment rooms and the fine art galleries. The installation, which is one of the largest, if not the largest, that has been carried out by this company, comprises 519 arc lamps of their usual 2,000 nominal candle-power pattern. These lamps are arranged on twenty separate circuits, each supplied by a separate dynamo, of which there are eight capable of lighting thirty-five lamps each, six suitable for twenty-five lights, and six suitable for fifteen lights. The outside circuits include seventy lamps, of which forty-five are mounted in groups of three, on wrought-iron tubular masts, sixty-five feet high, fitted with raising and lowering gear inside the mast. The general effect of this arrangement is good, but the grounds are too extensive to be satisfactorily lighted by the number of lamps employed. The remaining lamps of the Brush installation are placed inside the main building, and are arranged in rows, running along the middle lines of the various avenues. Each row of lamps is supplied from two separate circuits, alternate lamps being taken from each circuit. In this way a failure of one dynamo, or of one circuit, still leaves half the lamps lighted, and there is little chance of any part being left in total darkness. In order to prevent a lengthened stoppage of any circuit due to the failure of a dynamo, three spare dynamos are provided, and are kept running, so that the faulty dynamo can be taken off the circuit and another substituted in a few seconds. The dynamos are connected to the various circuits through pairs of flexible leads to facilitate such a change. The dynamos and lamps are of the ordinary Brush type, and are too well known to require any special description in these columns. The actual aggregate lighting power of the lamps is such as to give about one candle-power per square foot of floor space.

The Fine Art Galleries are lighted by the Thomson-Houston arc lamps, the contractor being Mr. Richard Miller, of Glasgow, who acts as agent for that company. The installation consists of two circuits of twenty lamps each, and both circuits pass completely round the galleries, alternate lamps being taken from different circuits, so as to avoid as much as possible the risk of any part being thrown into darkness by an accident to either of the circuits or dynamos. These two circuits are supplied with current from two of the Thomson-Houston spherical armature dynamos, fitted with constant-current regulators, already frequently referred to in these pages. A third dynamo is kept in readiness for an emergency, and is so arranged that it can be instantly thrown on to either of the two circuits.

The first-class refreshment rooms are lighted by Edison-Swan 16 candle-power incandescent lamps, the contract for the supply of which has been secured by King, Brown and Co., Rosebank Electric Works, Edinburgh. The installation consists of 750 lamps, which are for the most part suspended in arched rows from the cross-beams of the roof, and fitted with tulip-shaped reflectors of amber and ruby coloured glass. These lamps are lighted by current from three dynamos, each capable of supplying 250 lamps. Fifteen circuits are used for conveying the current from the switch-board through the different rooms and back, and a circuit from each dynamo passes through each room. In this way only one-third of the lamps in any room is supplied from each dynamo or by one circuit, and hence it is unlikely that by any ordinary accident more than one-third of the lamps will be extinguished at any time. The circuits are arranged so that each lamp has the same electrode or leading wire resistance, which, with properly selected lamps, insures equality of brightness all through the rooms and avoids the bad effect of having under or over incandesced lamps in close proximity to those of normal brightness. In this case, as in the others, a spare dynamo is kept running, and can be made to take the place of either of the others almost instantly. A very convenient and effective switch-board is used in this installation, the arrangement of which is shown diagrammatically in Fig. 1. Referring to the diagram, D_1, D_2, D_3, D_4 represent the leads coming from the four dynamos; these are respectively connected to one set of terminals of four switches, A_1, A_2, A_3, A_4, the other terminals of which are connected to the

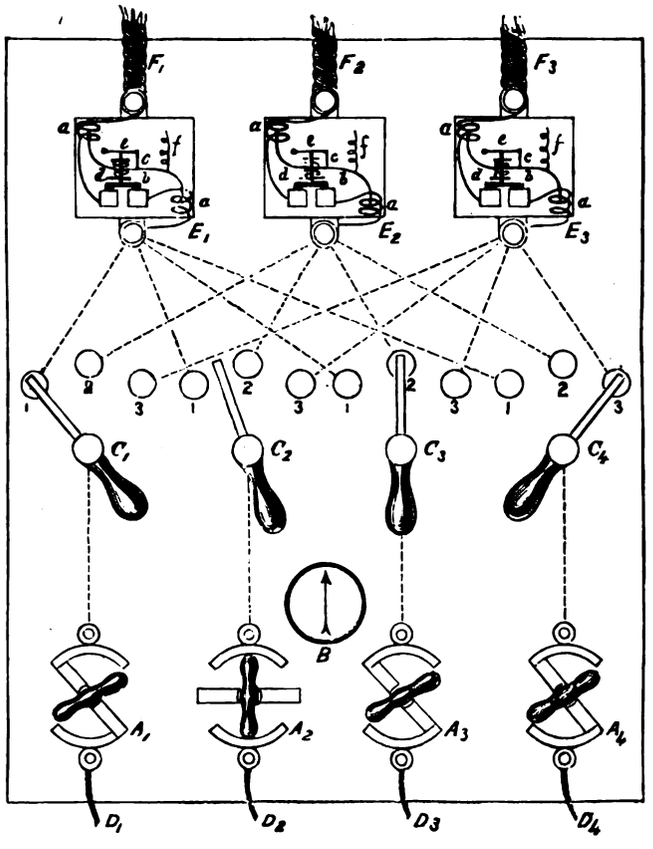

FIG. 1.

central studs of four lever switches, C_1, C_2, C_3, C_4. Each of the last-mentioned switches is provided with three contact plates, which are connected to one set of terminals of three electro-magnetic cut-outs, E_1, E_2, E_3, in the manner shown by the dotted lines in the diagram. To the other terminals of the cut-outs the groups of leads to the circuits supplied by each of the three dynamos that are supposed to be in action are connected. From the diagram it will be seen that should any dynamo fail, all that has to be done is to turn the spare dynamo (supposed to be D_2) on in its place by turning C_2 into contact with the proper contact plate, and closing the switch A_2. An ampere meter, B, is fixed on the switch-board, and fitted with flexible electrodes, so that it can be used to measure the total current flowing through the circuit of any one of the dynamos by putting the electrodes to the terminals of the proper switch, A_1 A_2, &c., and breaking the ordinary cross-connection of that switch. The general plan of the electro-magnetic cut-outs is indicated at E_2, where *b* represents a bent bar of soft iron surrounded at its end by two or three turns, *a a*, of the leading wire. The soft iron bar is held in position by an adjustable

Digitized by Google

spring represented by *f*, and carries a catch, *c*, which, by means of a lever, *e*, holds a bridge, *d*, into two cups of mercury, thus closing the circuit. When the current reaches a certain strength the bar *b* is deflected, the lever *e* is relieved, and the bridge *d* is then shot up out of the mercury cups by a spring on the vertical spindle.

The motive power for the electric lighting is obtained from twelve steam engines of various sizes supplied by Robey and Co., Lincoln; A. and W. Smith and Co., Glasgow; Greenwood and Batley, Leeds; Adamson and Co., Dukinfield; and Alley and M'Lellan, Glasgow. The Brush Company's dynamos are for the most part driven through four sets of countershafting by means of four powerful engines. The Thomson-Houston dynamos are separately driven by belting direct from high-speed engines of about twenty-five horse-power each, supplied by Robey and Co. The King-Brown dynamos are driven by two Westinghouse engines of 75 and 63 horse-power respectively, each driving two dynamos directly by belts.

ELECTRICAL POWER APPLIED TO RAILWAYS.—THE BEAUMONT GEAR.

In our impression of the 1st inst. we published an article on this subject by Mr. Coerper, of Cologne, in which he described an arrangement of motor for tramcars, designed to permit the rotation of the armature when the car axle to which it is attached is either standing still or being brought to rest, or is being gradually put in motion from a state of rest. In another part of the same impression we commented upon the arrangement described as appearing to be in effect a form of friction clutch. Since then our attention has been further directed to this subject, and to a form of gearing devised to meet the necessities of tramcar requirements, and illustrated in *The Electrician* of the 10th September, 1886. This is the epicyconoidal gear designed by Mr. W. Worby Beaumont, and is sufficiently illustrated by the accompanying woodcuts, which we reproduce for the convenience of our readers. For propelling tramcars it is very desirable to be able to vary the relative velocities of the motor spindle and car axle without loss of power or without doing lost work. To this end it must be possible to employ the full power of the motor at normal speed, whilst the car is moving much below normal speed, as when climbing a hill or in starting; or, to employ a common form of expression, it is necessary to be able to reduce speed to gain power. If any form of friction clutch or brake is used to permit the change of relative velocities, the extra power that is sought with the reduction of speed of the driven part is not obtained, but is absorbed by the friction attending the lost motion. The power of changing the relative velocities is secured and the shock to the motor and gear is reduced, but the main object, namely, variability of the propelling power, is not attained. If this had not always been the accompaniment of variable velocity gear, in which change is effected by varying the rate of relative velocities between frictional surfaces, any of several forms of frictional gear well known to mechanicians could have been brought into use long ago. In Mr. Coerper's gear the whole of the frictional work done by or upon the brake on the armature shaft is lost work. In the gear we illustrate this loss is prevented. Our engravings show one form of the complete gear as designed for tramcar use, and are sufficient for the present purpose. Fig. 1 is a plan of the gear, Fig. 2 an elevation, and Fig. 3 an end view. For the full engravings we must refer readers to the impression already mentioned. In the above illustration the primary shaft is seen at S. Upon this are mounted a cone, K, capable of longitudinal movement on the shaft, and carried by means of a spherical joint, the externally geared wheel B, the excentric C (Fig. 2), the pinion D, and the internally geared wheel A, the last being also provided with teeth at J for conveying motion at the varied velocities by means of a pitch chain. The wheels A and B are both loose upon the shaft S, which may be a continuation of the motor spindle or driven therefrom. They are also both provided with internal teeth, B having, say, three less teeth than A. As D (Fig. 2) rolls round in gear with the teeth of both wheels, one being held fast, motion is communicated to the other. This, if B is held fast, A will revolve at the maximum speed due to relations between the numbers of teeth, &c. But if B is allowed to rotate at a greater or less speed, so much speed will be taken from A. Gearing with the external teeth of the wheel B is the pinion E, which is fixed upon the spindle H of the wheel F, which runs in frictional contact with the cone K. Running upon the excentric C (Fig. 2) is a pinion, D, which gears with the internal teeth of the wheel A and with those of the wheel B. The wheel F is held by a brake, X (Fig. 1), which is put into or out of gear by the movement of a handle, R, which changes the position of the cone by means of rod R′, which moves the carriage M and fork Q. As shown in the engraving (Fig. 2), the wheel F is not touching the cone. It is fixed when the cone is in the position shown, and therefore the wheel B is held stationary by the pinion E, which is on the same spindle. The cone in this case is inoperative, and the maximum velocity is imparted to A. Now, if the brake X which fixes F be withdrawn and the cone be brought into contact with the peri-

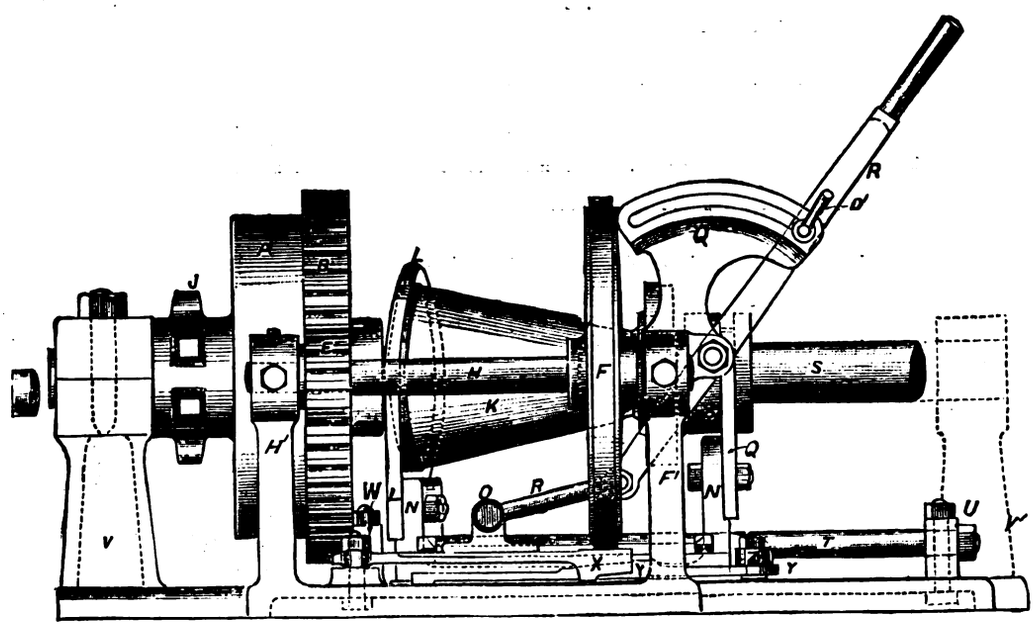

FIG. 1.

Digitized by Google

phery of F, the wheel B will be permitted to rotate at a velocity depending upon the ratio of the diameters of the cone and wheel F, and of the pinion E and wheel B. When the wheel B rotates, the velocity of its rotation is taken from that of A, and the velocity of A will therefore vary in proportion to the larger and smaller diameters of the cone.

Inasmuch as the work done on E by the permissive rotation of the wheel B is given up to the cone K by the wheel F there is no loss of work, as there would be if B were permissively rotative by allowing it to slip in a brake.

It may perhaps be necessary to mention that the cone K is hollow, and is, in the form shown, carried in the boss P by means of a spherical joint. It thus, in rotating with the spindle S, always maintains the position shown, except that it is movable along the spindle, so as to rotate the wheel F at a higher or lower velocity.

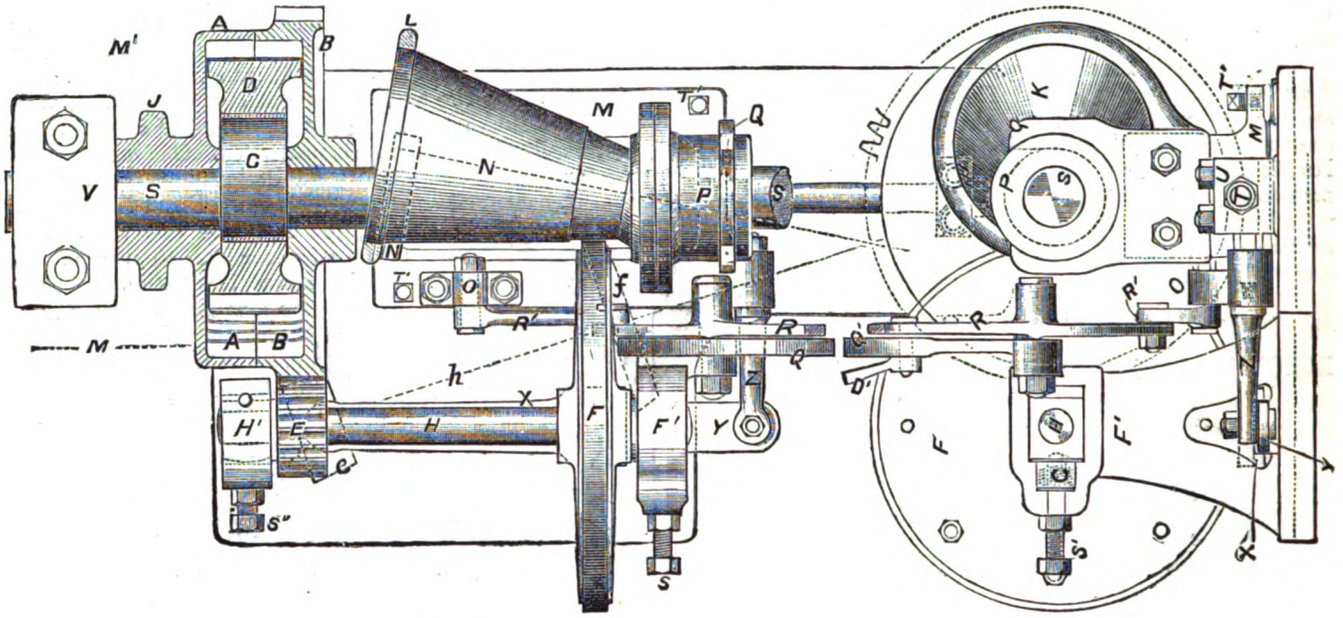

FIG. 2.

FIG. 3.

DELANY'S IMPROVEMENTS IN SUBMARINE CABLE TELEGRAPHY.

A system of submarine cable working which would permit the employment of ordinary Morse signalling has long been sought for. If a submarine cable of any length could be worked at the maximum rate of hand-signalling with the Morse key, this would be more than equivalent to doubling the rate of transmission attainable with the Thomson mirror or recorder. The nature of the difficulties which have to be encountered in expediting the rate of signalling upon submarine cables is too well understood to need any recapitulation here. It will be sufficient to remark that if it were possible to transmit Morse signals by means of a succession of very brief currents of alternate polarity, *and all of equal duration*, the rate of working would be materially increased.

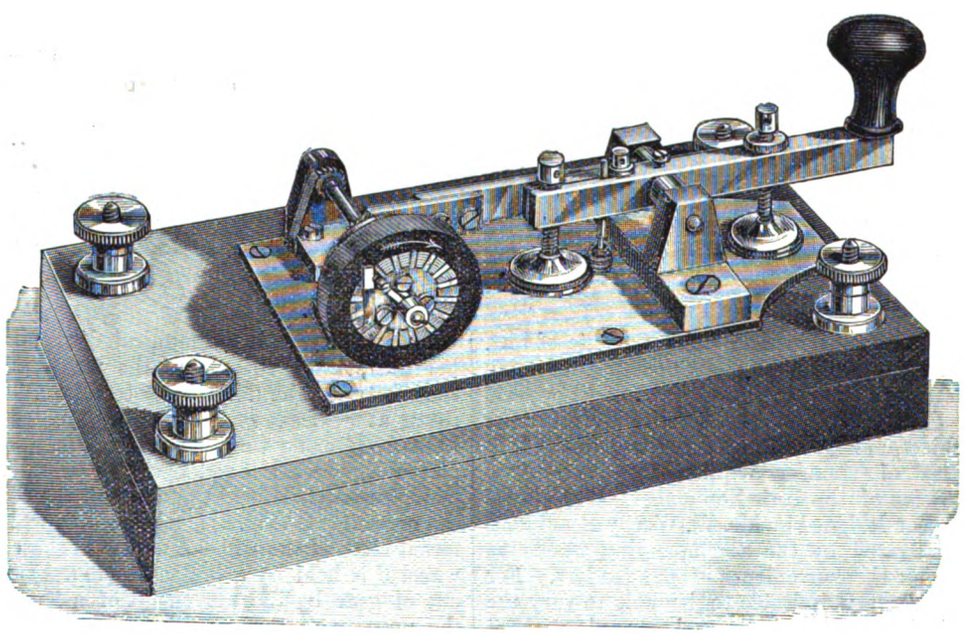

FIG. 1.

It is from this point of view that the problem has been attacked by Mr. Patrick Delany. The special features of his system are confined to the transmitting key, which we shall

Digitized by Google

presently describe. But we ought first to say that in the autumn of last year Mr. Delany was permitted to make some preliminary trials of his system over an underground cable belonging to the Postal Telegraph Department in this country, and it was at once evident that a step had been made in the right direction. The transmitting key used in these experiments remains in the possession of Mr. Preece, through whose courtesy we are enabled to produce the engraving (Fig. 1) in which it is illustrated.

It will be seen that the instrument consists of an ordinary Morse key which, by means of a pawl and radial wheel, causes the step-by-step rotation of a trailing contact arm. The arm consists of a slit steel spring, and it makes contact upon a steel disc built up of segments. The central boss of this disc is star-shaped, and the space between each radial arm is filled by an insulated segment which is about twice the width of the arm itself. The central boss with its radial arms is connected through a condenser to earth. The insulated segments are connected alternately to the positive and negative terminals of the battery respectively (the middle cell of the battery being to earth), and the trailer is connected to the line. When the key is at rest and making contact *either with the front or with the back stop*, the trailer is in contact with one of the narrow radial arms of the disc, and

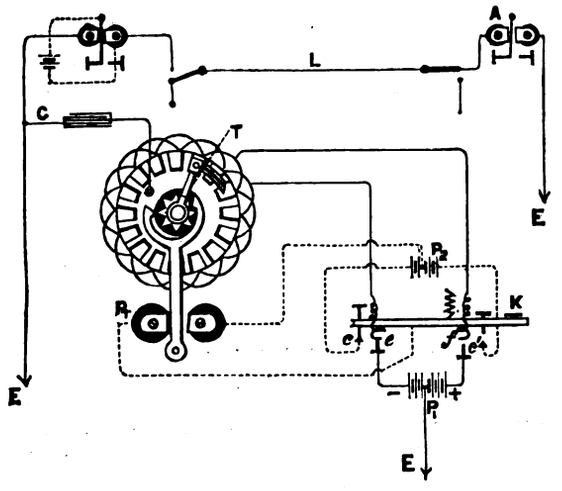

FIG. 2.

is therefore in a position to permit a condenser discharge to line. When the key is depressed the trailer moves across the intermediate battery segment to the next condenser segment. But the ratchet wheel is so connected that the trailer transfers the line from one battery segment to the other *in advance* of the movement of the key. In passing from a battery segment to the condenser segment the trailer connects the two together for an instant, thereby charging the condenser with the same polarity of current sent to the line. While the trailer is passing over the condenser segment *alone*, the condenser discharges into the line its induced current of opposite polarity, which meets and neutralises the static discharge coming out of the line or cable, and thereby leaves the cable perfectly clear for the next signal impulse. It will therefore be seen that there are no dashes sent into the line, that all currents are of equal duration and alternating in polarity. The capacity of the condenser is readily adjustable to the discharge from the cable. The duration of contact between the battery and line may be regulated by adjusting the key.

If the system should come to be employed by the English cable companies it is probable that the method of working direct from the key, as already described, would be preferred. In America, however, the use of a polarised relay as a repeater at the transmitting station is much in vogue. Mr. Delany has therefore adapted his device to this method of working, and in Fig. 2 we have a diagram of the circuit connections thus arranged. The following description of this diagram is taken from a recent article in the *Electrical World* of New York, and will probably assist in making clear anything not already fully explained:—

"It will be seen that the line L is connected to the trailing finger T, which moves from one segment to another at each reversal of the local current which controls the escape armature of the polar transmitter P T, all being under control of the single Morse key K. There are three groups or sets of segments in the circle, the battery-connected segments being joined to opposite poles of the main battery P_1. The intervening segments are all projections from a single plate which is connected through a condenser C d to earth. In the position shown the key is up or "open," the armature of the polar relay shown as a receiver at A is on the open side, and the trailing finger rests on a segment, which, if the key be pressed down, is put in connection with the positive pole of the main battery. As the key is open there is no current going to line. Now if the key be pressed down the connection to the positive pole of the main battery is first made at the spring contact f^1, but only for a moment, however; for, as soon as the key lever reaches its limiting stop c^1 the local battery P_2, through the polar transmitter P T, is reversed and the trailing finger

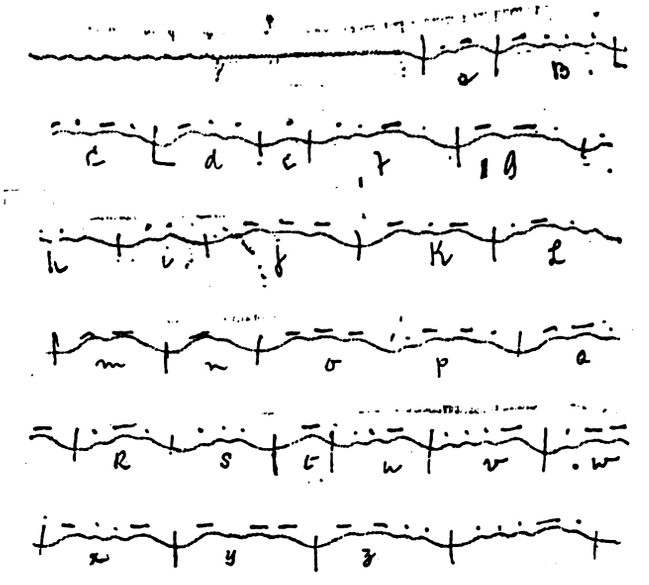

FIG. 3.

(line) is moved to the next battery segment, which finds its battery connection through spring contact e^1 at the back end of the key. So long as the key is held down this negative battery cannot go to line; therefore if the key be held down for the time represented by a dash the armature of the polarised relay at the receiving station, which went to its right hand or "marking" limit when the key was *first* pressed down, will remain there and keep the sounder circuit closed; and thus there is a continuous dash, although the line was disconnected from the battery as soon as the key was pressed down to its limit. Or, differently stated, when the key is pressed down a current of one polarity is sent. If it is immediately lifted up a current of opposite polarity is sent, lasting for the short time between the downward and upward movement, forming a dot. If the key be held down a dash is formed, not by the passage of a long impulse, but because the opposite polarity which terminates each signal is deferred until the key is lifted up. One current is the beginning of all signals, the other is the ending; the time between the beginning and the end determines whether the signal is a dot or a dash."

Fig. 3 is a facsimile reproduction of the Morse alphabet as transmitted by this system over an American cable 1,000 miles in length. The copper resistance of this cable is about 13,000 ohms, and capacity 900 microfarads. Fifteen Fuller cells were used for the experiment, although the cable is usually worked with twice that number of cells. The zigzag line at the beginning shows dots, and their perfect uniformity and clearness may certainly be taken to justify the expectation that the rate of signalling on long cables may be decidedly improved by the application of a system of regular reversals.

The curves given on the preceding page are taken from an interesting Paper in the current number of the *Centralblatt für Elektrotechnik*, by Herr W. Fritsche, of Fritsche and Pischon, Berlin. Curve I. shows the actual total cost of an installation for outputs varying from *nil* to the maximum. The fixed charges are of course the same for all outputs, the principal variation being for fuel. Figs. 2—11 show the hourly variation from month to month throughout the year both with regard to output and cost, and hardly require any explanation. The

GASSNER'S DRY BATTERY.

Various attempts have been made from time to time to do away with the necessity for the presence of a liquid electrolyte in the voltaic cell, but hitherto very little success has been attained. The use of sand or sawdust, or similar substances, to absorb the liquid has not been attended with satisfactory results; it adds considerably to the internal resistance, it necessitates more frequent attention to the cell, and renders that operation, if anything, more messy and troublesome than before. Moreover, it increases the tendency to polarise, and does nothing to prevent the creeping of the salts held in solution and consequent corrosion of the terminals.

In a cell of this type which has been devised by M. Gassner, it is, however, claimed that all these difficulties have been overcome, and judging from the reports of the tests made by Prof. Gerrard at the University of Liége, and from the success which the battery has already attained in practical use, we are inclined to believe that an improvement of considerable value has been attained. The cell is made up in a very compact form, and the outer case being of zinc (forming the positive plate), the danger of breakage is entirely done away with. Compared with the Leclanché cell, the current is much more constant, and weight for weight the battery has a much larger output. The cells can also be placed in any position, and being well varnished on the outside may even be packed one on top of the other; so that the combination is of a very portable character.

The exact method in which the electrolyte is made up is kept secret; but we understand that gypsum, or sulphate of lime, is employed as the medium of suspension, and that protoxide of zinc forms one of the chief ingredients. The electrolyte forms a dry and compact mass, which is yet sufficiently porous to allow the evolved gases to escape with freedom. The E.M.F. on open circuit is 1·5 volt.

The most remarkable peculiarity of the cell has yet to be mentioned. After having been run down to 0·1 volt, by passing a current through it in the reverse direction, it can be recharged just like a secondary cell. This operation can be repeated several times, the possible number of repetitions depending chiefly, we presume, upon the dimensions of the positive element. The cell tested by Prof. Gerrard was of circular pattern, 7in. in height and 3in. in diameter; the following is an extract from his report:—

"Tests of the Gassner dry cell by Prof. Gerrard. Electromotive force at starting, 1·508 volt. Internal resistance, 0·21 ohm. The element was put on short circuit:—

Time.	E.M.F. (Daniell's.)	Time.	E.M.F. (Daniell's.)
0	1·508	5 minutes	0·632
5 seconds	1·36	7 ,, ...	0·567
1 minute	0·935	10 ,, ...	0·525
2 minutes	0·800	15 ,, ...	0·433
3 ,, ...	0·682		

"It was then put on open circuit, and recovered itself as follows:—

Time.	E.M.F. (Daniell's.)	Time.	E.M.F. (Daniell's.)
1 minute	0·641	4½ minutes	0·832
2 minutes	0·750	5 ,, ...	0·850
3 ,, ...	0·791	3 hours 30 minutes	1·265
4 ,, ...	0·800		

"The element was again put on short circuit for 18 hours; the E.M.F. fell to 0·1015 volt. After this test, during which it had furnished work equal to 3·376 kilogrammeters, or 45 electric horse-power [·0125 horse-power-hours], it was left to rest, and recovered itself as before, showing that it was not exhausted.

Time of Rest.	E.M.F.	Time of Rest.	E.M.F.
10 minutes	0·172	45 minutes	0·289
20 ,, ...	0·234	19 hours	0·312
30 ,, ...	0·242	24 ,, ...	0·625

"After this, the regeneration of the element by charging in the same manner as an accumulator cell was attempted, with the following results:—

Time of Charging.	Current.	E.M.F.
1 minute	5 amp.	1·13 volts.
3 minutes	,, ...	1·20 ,,
5 ,, ...	,, ...	1·29 ,,
7 ,, ...	,, ...	1·305 ,,
10 ,, ...	,, ...	1·330 ,,
20 ,, ...	,, ...	1·425 ,,
30 ,, ...	,, ...	1·680 ,,
45 ,, ...	1 amp.	1·71 ,,
65 ,, ...	,, ...	1·92 ,,
75 ,, ...	0·8 amp.	1·89 ,,
4 hours 20 minutes	0·75 ,, ...	2·00 ,,

"Having thus raised the E.M.F. very considerably, starting from 0·1 volt, and running up to 2 volts, the element was next put on short circuit again, three minutes after removal from the charging cells, the E.M.F. then varied as follows:—

Time of closed circuit.	E.M.F.	Time of closed circuit.	E.M.F.
0	1·87 volts.	5 minutes	1·092 volts.
5 seconds	1·745 ,,	6 ,, ...	1·005 ,,
1 minute	1·54 ,,	7 ,, ...	0·940 ,,
2 minutes	1·338 ,,	8 ,, ...	0·886 ,,
3 ,, ...	1·285 ,,	15 ,, ...	0·770 ,,
4 ,, ...	1·100 ,,	18 hours 15 minutes..	0·100 ,,

"The efficiency of the element is calculated at 92 per cent., it having given back that amount of the current put into it during the regeneration. Two regenerations followed by successive discharges were tried; in each case the E.M.F. was

Digitized by Google

brought higher, and the polarisation less than that of a new element. The pasty mass between the carbon and zinc is not liquefied during the regeneration. After the last regeneration, followed by the putting on short circuit, the E.M.F. was let down to 0·107 volt; after resting for 25 hours it rose again to 0·64 volt.

"These tests show that a regenerated element is much better even than a newly-formed one by the ordinary process."

We have only to add that the battery is being introduced by Messrs. J. T. Mayfield and Co., of 41, Queen Victoria-street, E.C.

LETTERS FOR LEARNERS AND UN-PROFESSIONAL READERS.

BY H. D. WILKINSON.

CHAPTER IX.—*Magnetic Fields.*

(Continued from page 211.)

116. "*Moment*" *of a* "*Couple.*"—When there are two equal parallel and opposite forces acting on a lever, each force tending to turn the lever in the same direction, we have what is termed in mechanics a "*couple*," and by what has been said above it will be understood that the "*moment*" *of a* "*couple*" *is equal to one of the forces multiplied by the perpendicular distance between them.*

The "moment" of the "couple" in Fig. 75 is

$$F \times \text{the perpendicular } DD' = F \times L \sin a,$$

as given above.

The "moment" of the "couple" in Fig. 76 is F L. The unit

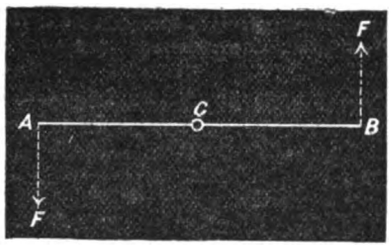

FIG. 76.

"moment" in the C.-G.-S. system is the dyne-centimetre—that is the moment of a force of one dyne acting at a perpendicular distance of one centimetre from the turning centre of a lever would be of unit value. Similarly, half a dyne acting at two centimetres distance, or ten dynes acting at one-tenth of a centimetre distance, would be of unit moment.

117. *The* "*Couple*" *due to the Earth's Field.*—Returning now to the magnetic needle (of strength of pole = m) capable of turning about its centre in the uniform magnetic field H, we know that the mechanical force acting at each end of the magnet is equal to H m dynes. These two forces then constitute a "couple," and we can now determine the moment of the couple exerted upon the magnet in any position in which it may be placed in the field. For example, when the magnet is in the meridian (Fig. 72) there is no moment at all, although the forces are acting at each end of the magnet. There is no perpendicular distance between their directions, since they are acting in the same straight line, like the opposite sides in a "tug of war." Now, when the magnet is at right angles to the lines of force of the field (Fig. 73) the moment of the couple is a maximum, and is equal to H $m l$ dyne-centimetres, where l is the length of the magnet expressed in centimetres. If, however, the magnet is in some intermediate position (as in Fig. 77) the moment of the couple is

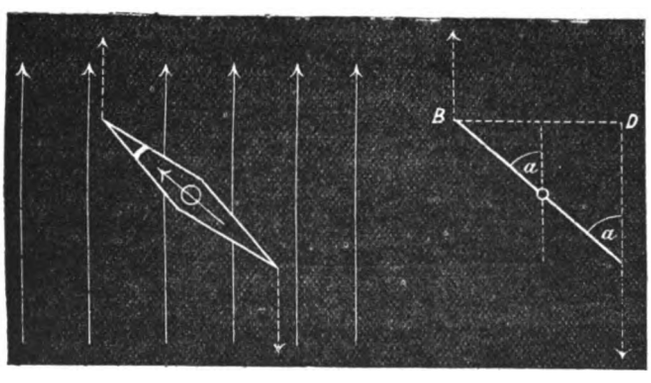

FIG. 77,

$$\text{H } m \times \text{the perpendicular B D.}$$

Now, the two angles marked a are equal to each other, and indicate the angle between the needle and the meridian, and we have the relation

$$B D = l \sin a;$$

hence

$$\text{moment of couple} = H\, m\, l \sin a.$$

Again, if the needle is displaced from the meridian more than a right angle (as in Fig. 78), and we still call a the angle between the needle and meridian, we have

$$\text{moment of couple} = H\, m \times B D = H\, m\, l \sin a.$$

Hence in whatever position the magnetic needle is placed, if we call a the angle by which it is displaced from the meridian, we have the moment of the couple tending to restore it to the meridian equal to

$$H\, m\, l \sin a.$$

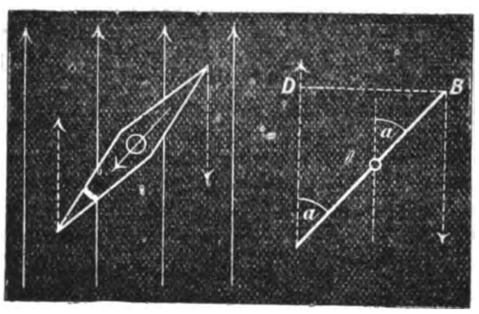

FIG. 78.

Example.—A magnetic needle whose strength of pole is 20 C.-G.-S. units and length 6 centimetres is moved 60 degrees away from the meridian; what is the moment of the couple tending to restore it to the meridian (H = ·18 C.-G.-S. units)?

$$\text{Moment of couple} = \cdot 18 \times 20 \times 6 \times \frac{\sqrt{3}}{2}.$$

$$= 18{\cdot}66 \text{ dyne-centimetres.}$$

What is the moment of the couple when the needle is 90 degrees from the meridian?

Ans. ·18 × 20 × 6 = 21·6 dyne-centimetres.

What mechanical force must be applied at right angles to this needle and *at one end* of it to keep it in equilibrium at 60 degrees?

Here the moment of the force F applied at one end is $F \frac{l}{2}$, and this must equal the moment of the couple due to the earth.

Hence

$$F \times \frac{6}{2} = 18{\cdot}66,$$

and

$$F = 6{\cdot}22 \text{ dynes.}$$

If this force was applied by attaching a thread to one end of the needle, passing it over a small frictionless vertical

Digitized by Google

pulley, and hanging a weight on the end of the thread, what weight would this have to be?

$$\text{Weight in dynes} = \text{mass} \times \text{acceleration of gravity} = \text{mass in grammes} \times 981$$

and this must equal the force of 6·22 dynes.

Therefore

$$\text{mass required} = \frac{6{\cdot}22}{981} = {\cdot}00634 \text{ gramme.}$$

Now the gramme mass is equal in weight to 15·43 English grains. Hence

$$\text{weight required} = {\cdot}00634 \times 15{\cdot}43 = \frac{1}{10} \text{ grain nearly.}$$

(To be continued.)

ON THE CHANGE OF POTENTIAL OF A VOLTAIC COUPLE BY VARIATION OF STRENGTH OF ITS LIQUID.*

BY DR. G. GORE, F.R.S.

This paper contains a series of tables of measurements of the electromotive forces of a voltaic couple composed of unamalgamated zinc and platinum in distilled water, and in aqueous solutions of different strengths of the following substances:—Potassic chlorate, potassic chloride, hydrochloric acid, and bromine. The measurements were made by balancing the potential of the couple by that of a suitable thermoelectric pile† (*Proc.* Birm. Phil. Soc., Vol. IV., p. 130; *The Electrician*, Vol. XII., p. 414) through an ordinary astatic galvanometer of about 100 ohms resistance.

The following are the minimum proportions of those substances required to change the potential of the couple in water:—Potassic chlorate, between 1 in 221 and 258 parts of water; potassic chloride, between 1 in 695,067 and 1,390,134; hydrochloric acid, between 1 in 9,300,000 and 9,388,185; and of bromine, between 1 in 77,500,000, and 84,545,000 parts.

With each of these substances, a gradual and uniform increase of strength of the solution, from the weakest up to a saturated one, was attended by a more or less irregular change of electromotive force.

By plotting the quantities of dissolved substance as ordinates to the electromotive forces as abscissæ, each substance yielded a different curve of variation of electromotive force by uniformly increasing the strength of its solution, and the curve was characteristic of the substance. As the least addition of a foreign soluble substance greatly changed the "mininum point" and altered the curve of variation of potential, both the curve and the minimum proportion of a substance required to upset the balance of the couple in water may probably be used as tests of the chemical composition of the substance, and as means of examining its state of combination when dissolved. By varying the strength of the solution at each of the metals separately, a curve of change of potential was obtained for each positive metal, but not for every negative one.

* Paper read before the Royal Society, June 14, 1888. Abstract.

† This instrument is manufactured by Messrs. Nalder Brothers, Horseferry-road, Westminster.

THE UNITED TELEPHONE COMPANY BILL.

DEPUTATION TO THE POSTMASTER-GENERAL.

An influential deputation waited last week upon Mr. Raikes, the Postmaster-General, to ask him to support the reference of the United Telephone Bill to a Select Committee. The object of the Bill is to afford additional telephonic communication throughout the kingdom. The deputation was introduced by Sir John Lubbock, M.P., and included the following members of Parliament:—Messrs. Quilter, Robertson, Jacob Bright, T. A. Dickson, Murphy, Whitley, Bonsor, Colonel Anstruther, R. Heath, and Richardson; the Chairman of the Telephone Company (Mr. James Brand), the Deputy-Chairman (Mr. J. S. Forbes), and the General Manager (Mr. J. Morgan).

Mr. FORBES stated the case for the Company, and dwelt upon the facilities which had been given to the Hydraulic Power Company, the gas and water companies, and other semi-public institutions, compared with the restraints and hindrance which had been put in the way of the telephone companies, who were often subjected to very great and unreasonable complaints on the part of the public for imperfect communication when, in reality, it was chiefly owing to the want of proper facilities.

Mr. DICKSON, as a member of the committee of 1887, spoke of the strong feeling which had found expression in the report of the committee, and an industry of this kind should be fostered and encouraged, instead of being hindered by the Post Office, who, by some accident, had acquired a legal right to control the telegraphs.

Sir W. H. HOULDSWORTH, M.P., spoke of the great importance of the development of this system to Lancashire.

Mr. JACOB BRIGHT asked for some distinct statement as to what the Government were prepared to do in the question.

The POSTMASTER-GENERAL, in reply, said that he had consulted with some of his colleagues on the question of allowing the Bill of the United Telephone Company to proceed to the second reading. After this consultation he found himself compelled to state that the Government must oppose the second reading. The report of the committee, of which Mr. Dickson was a member, proposed a general Bill, and that whatever powers were granted to companies should also be given to the Postmaster-General. As a matter of fact, the present Bill related to a single company, which worked within a radius of 12 miles of the General Post Office, and it proposed to give this company considerably greater powers in the matter of overhead wires, &c., than the Postmaster-General himself possessed over the same area. He thought, therefore, that in any case, if any step was taken at a future period to confer all these facilities, it must be by a public and not by a private Bill. It was suggested that the present Bill might be extended in committee so as to effect this; but he thought that it would be much more satisfactory to deal with the matter at one time by means of a public Bill. At the present time, moreover, there were many questions before Parliament, especially the matter of the local government. As soon as that was disposed of he would take an early opportunity of laying the whole question before Mr. Ritchie, the President of the Local Board, with a view to the introduction of a public Bill. The matter should not be lost sight of.

According to the reports which appeared in *The Times* and other papers on the following day, Mr. Raikes added that the telephonic patents would expire shortly, and then the Government might be able to deal with the development of the telephonic system.

Afterwards a consultation was held, and the deputation decided to drop the Bill for this Session.

"INFLUENCE MACHINES, FROM 1788 TO 1888."

BY PROF. S. P. THOMPSON.

(Concluded from page 215.)

DISCUSSION.

Prof. AYRTON said he had listened with the greatest interest to the charming historical account that had been given them of the Darwinian development of a Darwinian idea. He did not think there was any one—certainly no other Englishman—who could have given them so complete an historical record of the development of the influence machine as Prof. Thompson (loud applause). The address was certainly on a par with the Paper which Prof. Thompson gave, some short time ago, to the Society of Arts, showing in the same complete way the development of another piece of apparatus of great value to electrical engineers, namely, the vacuum pump. There was one peculiarity in the history which he did not think that Prof. Thompson had sufficiently laid weight on. He (the speaker) had called it a Darwinian development, and as the author had described it, he thought one might fairly apply that term. It seemed to him that the peculiarity of this history was that, instead of the one machine developing out of the other—which was, of course, the Darwinian idea of progress—the subject had been re-invented over and over again, entirely *de novo*, without any knowledge apparently existing in the inventors' minds that anything of the same kind had been done before their time. He had occasion at the last meeting to speak of the marvellous inventive genius of the author of that Paper, Sir William Thomson. He did not think that, perhaps, the visitors would quite have grasped that evening that the same genius was really employed by Sir William Thomson in devising a machine which apparently is exactly the same as Belli's machine [see *Electrician*, June 8th, p. 152, Fig 6]. Belli's machine had every feature possessed by the ordinary Thomson replenisher, and it would not be very clear, therefore, to understand what great merit was due to Thomson for having, in 1867, made an instrument which had already been made in 1831, or about that time. But he himself happened to be with Sir William Thomson in 1867, and he knew the history of the development of the Thomson replenisher in the Glasgow laboratory. It was in no sense a development of any known electrical machine at that day. He did not know why, but nobody then seemed to know anything about what had been done before. Sir William

Digitized by Google

Thomson most certainly was not aware that any influence machine existed in 1867. He wanted to devise a machine which had been of great practical use up to the present date. Sir William Thomson wanted to make recording instruments practicable for submarine cables; he wanted to electrify the ink. As he said at the time. "I cannot bear the idea of employing coolies to grind frictional machines all day and all night long for the purpose of electrifying the ink"; therefore it became necessary to invent or devise some sort of apparatus which should produce the amount of electric energy in a far more economical way—which should have, in fact, a far higher efficiency, which should convert a given amount of mechanical energy into a far greater amount of electric energy. He started apparently without any knowledge of anything that had been done on the subject. After various trials he developed his well-known "replenisher," which appeared to be almost exactly like the Belli machine of 1831. Seeing what enormous value the machine might have for commercial purposes, Sir William proposed to patent it, and he asked the speaker and Mr. Bottomley to go and consult the Patent Office to see if by any remote chance anybody had ever done anything of the kind before. It was very curious, although Mr. Varley was not only a great friend of Sir William Thomson's, but he was practically a partner of Sir William's, yet so little importance had been attached to Varley's patent of 1860, and to any machines that Varley had made, that Sir William was not aware apparently that Varley had done anything in the matter, and to the astonishment of himself and Mr. Bottomley they came across Varley's patent—the patent of seven years before, and Sir William Thomson then saw that he had merely re-invented a machine which had been very completely described by Varley at that date. There was one thing he wished to ask Prof. Thompson or Mr. Wimshurst. It had been stated that if brushes were used for exciters and combs for the parts which he would call inductors, the machine did not reverse. His own experience was that it did, and he would like to know why it reversed so extremely easily. He did not think that the combs got over that difficulty. That was the great difficulty that Thomson had originally with his form of machine in 1868. He remembered a suggestion sent by Sir William to his instrument maker, Mr. White, of an arrangement for disconnecting certain contacts so as to prevent the possibility of reversing. The Wimshurst machine of the present day, without the Leyden jars, seemed certainly to reverse not unfrequently. Was it easy to avoid that in any simple way without the use of Leyden jars? He would also like to ask why machines made by instrument makers were very often so extremely inferior to those made by Mr. Wimshurst himself (laughter)? He had bought a machine some time ago of a certain maker who had advertised, and still advertised very freely, but it would not work at all; then Mr. Wimshurst supplied them with two plates that he had made himself, and it worked at times extremely well. Prof. Thompson spoke of experiments that had been made as to the efficiency of the various machines. It was most interesting to consider what these experiments have done. In 1857 he made some experiments in Sir William Thomson's laboratory on the relative efficiencies of a *plate glass frictional machine* which had an efficiency of point—he forgot how many noughts—and a Thomson's replenisher. Without going into figures, the enormous efficiency of the Wimshurst machine, as compared with the plate glass machines, was quite clear. Long after Mr. Wimshurst had ceased turning the machine exhibited that night the machine had kept on turning and the lightning had continued to pass between the knobs.

Mr. MORDEY said that in the very interesting diagram Prof. Thompson had shown them (Fig. 19) they saw on either side of the machine three pairs of plates that were apparently in the same state all through that part of the rotation. Would Prof. Thompson or Mr Wimshurst explain why that was so, and whether it would not be possible either to reduce the number of plates, or in some way to increase the effect produced by the machine by using the space so obtained.

Prof. HUGHES said that in the list of inventors given by Prof. Thompson the name of Mr. Bertsch, who in 1853 brought out at the Academy a very interesting influence machine, had been omitted.

Mr. C. E. GROVE, with reference to Prof. Thompson's statement that the Voss machine hardly ever reversed, said as a matter of fact the Voss machine was one of the worst machines for reversing. It did not depend, apparently, upon the mere relative position of the brushes and combs, but it also depended upon the position of the diagonal conductor, of which nothing had been said that evening. The liability to reverse could be increased or diminished by the position in which the diagonal conductor was placed.

Mr. A. J. WALTER: There is one question I should like to ask Prof. Thompson. Why on the diagram indicating the distribution of electricity upon the surfaces of the plates of the Wimshurst machine, no charge is depicted either on the inner surfaces of the plates opposite the points of the prime conductors, or upon the outer surfaces of the plates at the top and bottom of the diagram? Is it that on those portions of the plates there is no electrical charge, or is it that there is no free charge which can be collected at those points?

Prof. SILVANUS THOMPSON, in reply to Mr. Walter, said that his diagram was drawn to represent what one found at the different parts of the machine. At the top and bottom of the machine they found that the charges were of opposite sign, and therefore attracted one another toward the glass, and there was next to no free charge on the outside, whereas right and left on the one side positive, on the other side negative, they had both plates with charges of the same sign—he did not say absolutely equal in amount. The result was that instead of attracting each other towards the glass they repelled each other away from the glass, and they had all the charge virtually free. Perhaps when his paper was read in detail that explanation would be a little more clear. In reply to the question about the Voss machine, he certainly did not intend to indicate that the Voss machine never could reverse itself. All the Voss machines that he had seen had brushes where there ought to have been combs only. They had combs with a brush or two interpolated among them in the discharging apparatus, and that of itself was quite enough to make the machine unreliable from that point of view. Also he did not like in the Voss machine the arrangements of tinfoil all along underneath those paper plates; that seemed to him to be rather a mistaken construction. The Voss machine was simply a sort of intermediate form which would sooner or later die out, and it had made its way simply because the instrument maker had seen that a handy machine of that kind was wanted and made one up at a fairly reasonable price. But he did not by any means regard the Voss machine as the final outcome of all influence machines. Certainly he had found Mr. Wimshurst's machines much less liable to reverse. He had a Wimshurst machine once, which had both brushes and combs on the discharging part, which was always reversing. He had removed the brushes and left the combs only on the discharging part, and he did not know that he ever had it reversed; in fact, with his eight-plate machine the difficulty was to get it to reverse, he could not do it. If they took a big discharge out on each side it did not reverse. If they turned it first backwards and then forwards it did not reverse as a Holtz would do. Mr. Wimshurst had told him how it could be done, but he would not have found that out for himself. It was very simple. Simply take a bottle-full with a Leyden jar from one side; then discharge the machine by putting the knobs together while turning the machine the other way; then turn the machine the right way, open the discharging knobs, and empty the charge of the Leyden jar into the other side from that which it was originally taken.

Prof. AYRTON said it had just occurred to him that this was a question of capacity, and that the large machines might not reverse, but he had been speaking of small machines, and the small machine Mr. Wimshurst lent him constantly reversed. It was a two-plate machine. It excited itself quite easily, worked extremely well, but reversed occasionally.

Prof. THOMPSON said, with respect to the position of the diagonal conductor, the liability to reverse in a Voss machine was certainly greater when the diagonal conductor was more nearly horizontal. When the diagonal conductor was in its proper place it greatly concentrated the stationary charge of the field-plates upon their extreme ends. When, however, the diagonal conductor was not opposite the end of the field-plate, then they did not have that concentration of field at either end, they had it further back; and the carrier, after having passed the most concentrated part, was still passing the field-plate with the same electrical sign upon it. The consequence of that was that they would have a greater tendency to instability if any instability were set up by a sudden discharge of one side. It was not, however, in his own mind very clear altogether what that instability depended upon. Prof. Hughes had asked why Bertsch was not in the list of names that he had given, but he had a much longer list than he had thought it necessary to put upon the board, and that of Bertsch was amongst them.

Mr. WIMSHURST said he thought there were only two points that he had to answer—the first was, why makers of instruments failed in certain points. That certainly was too indefinite for him to answer. He really could not say unless he saw the machines and examined them, and found the precise faults. He was astonished at the reversal of the current in the machine to which Prof. Ayrton had alluded. Throughout his experience, running over several years, he had never found one such case. There was no difference in the action between a large machine and a small one, and the large machine which had been experimented upon that evening was freely the property of any person who could make it reverse if they chose to practise it the whole evening—in fact, it was impossible to make it reverse. The small machine, which he lent to Prof. Ayrton some short time since, had 6in. glasses, and it had never reversed whilst in his own possession; there must, therefore, be some slight disarrangement.

Prof. THOMPSON said that he had omitted to answer Mr. Mordey's question. He had asked why at the top and bottom of the machine the sectors remained in the same state of charge. He believed it was because in between the two ends of that range nothing was done to them; they simply passed one another in precisely similar conditions, and it was no gain to shift the two sets of neutralising brushes either way. What they wanted in a machine of that sort was the most complete insulation between the parts of opposite sign. It would be no advantage whatever to shift those neutralising brushes towards one another unless one could in some way lengthen the distance between the charges of opposite sign on the same face. The length of spark they could get out of a machine of this sort was practically limited by the distance across the plate in the interspaces between carrier and carrier. He could not conclude his reply without saying that although it had been a great pleasure to him to bring these instruments before the Society, it was much more to Mr. Wimshurst than to himself that this exhibition of apparatus was due. He had relied upon Mr. Wimshurst's kind offices from beginning to end to be able to show the Society the latest and best influence machines.

The PRESIDENT: Gentlemen, I am sure you will all agree with me that the very lucid and interesting discourse to which we have listened affords a striking proof of careful, exhaustive research on the part of its deliverer, forming a worthy tribute to the memory of the discoverers of electrical influence and deserving a most hearty vote of thanks; and I beg, therefore, to move that the cordial acknowledgements of the Society be presented to Prof. Thompson for the discourse he has been kind enough to give us, coupling with that the name of Mr. Wimshurst, who has furnished the remarkable apparatus of his own devising.

The vote of thanks was then passed, amid loud applause.

Prof. Thompson and Mr. Wimshurst then proceeded to further experiment with the machine with Leyden jars.

The proceedings then terminated, and the Society adjourned until November 8th.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *June 16th*, 1888.

The city of St. Louis has been recently the scene of a very lively controversy between the Telephone Company and the Local Government. Some few months ago the Corporation took upon itself to pass an ordinance making it a misdemeanour for any telephone company to charge more than $50 a year for the use of a telephone. The local company, which has given excellent law service under Mr. Durant, who is known to many of your readers, has been charging $100 a year; and as it did not intend to make any change, evidences of the "violation" of the ordinance were soon forthcoming. Thereupon the company was brought before the Courts, and fined $300 for alleged exorbitant charges. As the result of this, the directors of the company met, and resolved to make no more contracts in St. Louis until the constitutionality of the ordinance could be tested by the Courts of the State. The city officials propose to pull down the poles and wires in case the service be discontinued, and they have already received a direct challenge in the removal of the instruments from various public departments, including the Mayor's office. A great many of the subscribers, who own that they are getting the worth of their money, are very anxious to have the company continue in business, and have been offering to make up the old amount by donation. The telephone company, however, disdain to do anything that might seem like an evasion of the ordinance, and thus the matter stands at the present time. Now that St. Louis has enjoyed an excellent service for so long it is hard to believe that it will allow the company to be treated in this way, and the probability also is that the ordinance will not be found to be in keeping with the terms of the company's charter from the State, and will therefore be annulled. It is interesting to observe, as I have before remarked, how the conflict between the civic and the telephonic authorities shifts from city to city.

The holding of the conventions this year for the nomination of presidential candidates has afforded an admirable opportunity for the display of the electric light. The northern nave of the Exposition building in St. Louis, where the Democratic official convention has just been held, bringing together some 16,000 people, was illuminated by the Heisler system with very good results, lights of 30 candle-power being used. The big hall in Chicago, where the Republican Convention meets next week, has been fitted up with an equipment of 3,000 Edison lights, and the effect is said to be the finest of the kind ever seen. A notable feature is the illumination of two United States shields, around each of which several hundred incandescents are grouped at each end of the hall. It is said that the results are so magnificent that the conventions will have evening sessions for no other reason than to see the hall illuminated. Another very fine piece of lighting of this character is now being carried out at the Ohio Central Exposition, to be held at Cincinnati. About half a dozen systems, arc and incandescent, will be used under contract. Special arrangements have been made for the display of a number of new electrical effects, and it is said that every evening an electrical performance will take place, when owls will shine out in the darkness, flashes of lightning illuminate rainbows, electric flowers bloom in baskets along the roof, coloured fires glow under the fountains and cascades, crescents and constellations blaze out one after the other, and the whole scene will be lit up by an illumination such as has never been known on land or on sea before. The whole of this special work will be in charge of Mr. W. J. Hammer, who was for some time connected with the Edison Company in Europe.

The investigation which has been going on in this city by the coroner's jury for the last two or three weeks has been brought to a close by a verdict fixing the responsibility upon the local company, and condemning the lighting companies in general for their "parsimonious spirit" in not keeping up the insulation of their wires. The attention of the district attorney has also been called to the subject, and the jury flatters itself that it has done a useful piece of work. In the meantime the Mayor and the Board of Electrical Control have continued their janglings and wranglings over the subject of the wires; and while the Mayor has been persistent in his refusal to do anything with regard to the removal of the poles so long as there was no appropriation for the purpose, the Board is exercising its power to prevent the companies from contracting for new business. It is specially vigorous in its campaign against the local United States Company, which has given much offence by its steady refusal to obey the mandates of the Board on the ground that it was impossible to carry out such orders. One useful result of the whole agitation has been to direct attention to the "tramp" wires—*i.e.*, wires which have been abandoned, or were once the property of companies now defunct. These wires are by no means few; in fact, in a city like this there are probably hundreds of miles of them, and as every now and then they give way they are a source of incessant danger and trouble. I have no doubt that steps will soon be taken to clear them out. It would seem also that there are abandoned poles as well as wires. The attention of the Commissioner of Public Works was called this week to the fact that an iron telegraph pole has been standing at the corner of Broadway and Twenty-third-street for the last ten years, although it has not been in use by any company. It is both an eyesore and a nuisance, but its removal has never been attempted these long years, simply because it was nobody's business. Now, of course, it will go.

The use of electric motors on board men-of-war has already been discussed, but has never before been practically attempted, I believe. I now understand that the Sprague Company has received an order from the Government for motors, which will be put at once on board the new steam cruiser "Chicago," to be used in the training and elevation of the guns. The problems involved are of a very interesting nature, but I have no doubt they will all be most successfully grappled with. Another new use to which the Sprague Company will shortly put one of its motors is that of running a merry-go-round at a seaside resort.

I notice in your paper and others references to the new coulomb-meter recently patented by Prof. Elihu Thomson, and of which mention was made in this correspondence some weeks back. While I have nothing to say as to the questions of priority that have been raised, and which Prof. Thomson will probably deal with himself, it would not be out of place to offer passing comment on the assumption that is made in England, that because Prof. Houston published an article on another similar meter last December, it is singular that Prof. Thomson should have brought out his own so soon after and have had nothing to say about the parallelism. It deserves to be mentioned, I think, that while their names are closely linked in one of the leading systems, the two gentlemen have not, so far as I am aware, done any work together for some years. Prof. Houston resides in Philadelphia, engaged in educational work, while Prof. Thomson lives hundreds of miles away at Lynn, where he is busily occupied in connection with the Thomson-Houston Electric Company, of which he is the electrician. Probably the only gentleman with whom Prof. Thomson has collaborated of late years is Mr. W. Rice, who has charge of all the electrical work that the company turns out. Perhaps it does not add in any material way to the discussion that has arisen, but at the same time I take the liberty of saying for Prof. Thomson that, with all his great genius, he is one of the most modest and unassuming of men—a man as to whose sincerity and straightforwardness the briefest conversation with him would remove any doubt. It may even be that attributing to him the invention of this ingenious meter goes further than he himself would claim; but the fact that he has secured a broad patent on it, applied for months ago from our American Patent Office, is at least strong presumptive evidence in his favour.

While on the subject of co-operative arrangements in inventing, I might mention, on very good authority, what I am assured is not less true than it seems amusing, namely, that Ayrton and Perry are regarded in many parts of this country as being simply a very enterprising and successful firm of instrument

Digitized by Google

makers, whose wares are well advertised and in brisk demand; in fact, I am told that the firm who handle here the instruments designed by the two distinguished professors are often in receipt of orders for instruments of "Ayrton and Perry's make."

In the absence of competition, the Western Union Telegraph Company is now making a better balance-sheet than has been the rule during the last year or two. The net revenues for the June quarter are estimated at $1,350,000, and a dividend of 1¼ per cent. will be paid. It is thought that the earnings next quarter, which will include nearly all the activities of the political campaign, will show a net of not less than $1,600,000, and then the dividends may go up to 1½ per cent.

CORRESPONDENCE.

CLARK STANDARD CELLS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Having noticed your remarks in No. 520 of *The Electrician*, May 4th, 1888, with reference to Mr. Howell's Paper on "The Maximum Efficiency of Incandescent Lamps," and also the correspondence elicited thereon in your No. 525, of June 8th, I think the following facts not only bear upon the question at issue, but are also of interest to electricians everywhere, since they tend to show how closely independent standards of E.M.F. in the form of Clark cells carefully set up can be relied upon to agree, and that in fact it is only necessary for an electrician to be provided with a standard resistance coil in order to furnish himself through the medium of these cells with all the other electrical units in any part of the civilised world without recourse to special determinations in absolute measure:—

Three Clark standard cells set up in this country at the Edison Lamp Factory, Newark, N.J., under the supervision of Mr. Howell, were supplied to the Edison laboratory last January. They agreed and still continue to agree with each other within 0·00012 volt, or about 0·009 per cent. at the same temperature.

Two standard Clark cells set up in London under the care of Dr. Alex. Muirhead reached the laboratory on the 28th ult. These also agree with each other within 0·00010 volt at one temperature.

The difference between the E.M.F. of the Newark and the London cells is within 0·0004 volt, or 0·028 per cent., all at the same temperature, and the mean difference is about 0·00025 volt excess on the side of the London cells.

Precautions are necessary to maintain the cells at the same temperature during comparison, and it need hardly be pointed out that two Clark cells in close normal agreement, connected together in opposition through a galvanometer and set at different points whose temperatures between 0° and 40°C. are to be compared, constitute a very delicate differential thermometer.—Yours, &c.,

A. E. KENNELLY.

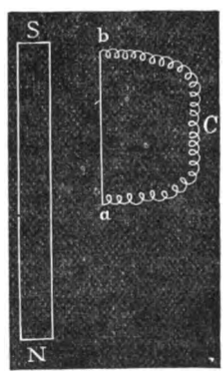
Edison Laboratory, Orange, N.J., 18th June, 1888.

UNIPOLAR INDUCTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. de Tunzelmann's interesting and instructive collection of data relative to so-called unipolarism will no doubt demand considerable attention, and it is with no wish to depreciate the value of such that I offer the following criticism. Mr. de Tunzelmann accounts for the phenomena noted by Faraday's law of electro-magnetic induction; but the explanations he gives by the aid of the typical diagram are not so convincing as might be. [The diagram is reproduced for convenience of reference: *a b* represents a section through the plane of the paper of a jacket surrounding the magnet N S] I here refer to the summary at the end of his last article, where, under heading No. 3, he states, that if the jacket and wire remain at rest whilst the magnet revolves there will be no current, because there is neither increase nor decrease in the lines of force cutting the circuit. Now I do not think this is altogether a very satisfactory explanation; no account is taken of the opposing E.M.F.'s that would be set up in the two paths of the current *b* C and *a* C, which are radial to the magnetic axis, and the assumption is that if that part of the circuit marked C were taken outside the influence of the lines of force current would be generated. If Mr. de Tunzelmann had returned his cylinders at one end towards the axis, as shown in the experimental diagrams, the explanation would have been more apparent. Considered in this light we have what are practically two conductors starting from a point near the magnetic axis. At *b* they branch and form circuit by two paths, one by *b* C and the other by *b a* to C, and herein lies the explanation; for with a little thought it will be seen that if two conductors, cut in any portion of their paths by symmetrical lines of force, —*i.e.*, by lines not increasing or decreasing in quantity— emerge from the same starting point in the field to form circuit outside, they must have the same intensity of E.M.F. induced in them, no matter how tortuous their paths may be in getting out, and as these E.M.F's will be opposed, there will naturally be no current.

Referring again to Mr. de Tunzelmann's diagram, it is noticeable that that portion of the circuit marked *b a* will, by



virtue of some of the lines of force cutting it, produce effective E.M.F. along its length, but that this will be neutralised by the opposing E.M.F. set up by the same lines cutting *a* C, so that we have practically only to deal with the lines that pass through and across *b* C and *a* C, which, as before stated, will produce opposing E.M.F.'s. If, however, the portion *b* C *a* of the conductor is stationary and the cylinder *b a* only revolves, as under heading No. 1, we shall then only have to deal with the lines cutting across *b a*, with the consequent production of current, as there will be then no opposing E.M.F. The above maxim would, nevertheless, hold good, as in this case the cut portions of the conductors do not extend beyond the influence of the field. The same reasoning can be applied to all the experimental data presented by Mr. de Tunzelmann, and will be found to be in accordance with the results in every case. In Fig. 8, when the magnets revolve and the galvanometer is placed between the terminals *a*, *c*, no current is obtained, and this is not because the cut portions of the two conductors start from the same point, but because they start from symmetrical positions in the field, or, what is the same thing, from points at equal distances from the poles; hence the E.M.F.'s are equal and opposed. If the cut portions of the conductors do not start from the same point, or from points situated symmetrically in the field, or where equal E.M.F.'s would be produced, current will result and be equivalent to the differences in their E.M.F.'s, always remembering that that portion of the circuit revolving with the magnet will be neutral and not cut by any lines of force.—Yours, &c.,

N. G. THOMPSON.

4, Queen Victoria-street, June 26th, 1888.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The account of a fire caused by lightning at the Narbonne telegraph station last week, as given in a paper I sent you, appears to have been exaggerated. I have obtained

Digitized by Google

some information on the subject, and what has happened is what, under similar circumstances, is almost certain to happen. Overhead wires, on entering the telegraph station, were attached, *through spur lightning guards*, to the gutta-percha covered wires leading to the interior of the station, and which were duly earthed during the thunderstorm. Upon a length of a foot, close to the terminals of the lightning guards, the copper wires became hot, and the gutta-percha dropped away but did not ignite.—Yours, &c., P. F. FEYTENS.

Marseilles, June 25, 1888.

[The paper referred to by our correspondent has not reached us.—ED. *E.*]

LEGAL INTELLIGENCE.

Swaby v. Watt and others.

In the Chancery Division of the High Court of Justice, on Friday last, the action by Lewis Swaby against Hugh Watt and others, directors of the Maxim-Weston Electric Company (Limited), came before Mr. Justice Stirling.

Mr. PEARSON, Q.C., counsel for the plaintiff, moved for an injunction to restrain the defendants from forfeiting or cancelling 400 shares of the company held by the plaintiff or allowing any notice, minute, or other entry alleging such forfeiture or cancellation to remain on the register or the minute-book of the board of directors.

Mr. GRAHAM HASTINGS, Q.C., counsel for the defendants, said he had received only on the previous night a long affidavit for the plaintiff.

Mr. PEARSON: It is simply an answer to yours.

Mr. HASTINGS: Very likely; but still I would like to read it.

Mr. PEARSON: But it is absolutely necessary that the motion be taken at once

Mr. HASTINGS asked for delay; but said that in the meantime he would undertake that his friend's client should not be interfered with in acting as a director.

Mr. PEARSON said that on the last occasion there was an undertaking given to produce to the plaintiff certain minutes. He had applied for them again and again, and could not get them produced.

Mr. HASTINGS: I am told a copy was made for you, so that there must have been some misunderstanding on that point.

His LORDSHIP then granted postponement on an undertaking by the defendants over next motion day that the plaintiff should have and exercise all the rights of a director of the company.

PATENT RECORD.

RECENT APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

8,751. T. J. WILMOT. Waterville. An improvement in the Wheatstone automatic system of telegraphic transmission by which it is adapted for use on submarine cables in connection with the "siphon recorder" and "mirror" system. June 15, 1888.

8,765. W. ROWBOTHAM and W. FOX. Manchester. Improvements in holders for incandescent electric lamps. June 15, 1888.

8,772. W. ROWBOTHAM and W. FOX. Manchester. Improvements in electrical switches. June 15, 1888.

8,784. F. V. ANDERSON and J. F. TAFE. London. Improvements in systems of electrical supply. June 15, 1888.

8,809. H. H. LAKE. London. Improvements in electrical switches (S. Bergmann, United States). June 15, 1888.

8,814. A. TREEBY. London. A new or improved magazine small-arm discharged by electricity, and cartridges for the same. June 15, 1888.

8,836. G. J. PHILPOTT and G. H. ALDERTON. Brighton. Improved safety electrical switch and fuse-box combined. June 16, 1888.

8,864. D. A. AIRD. London. An electric tell-tale or counter mechanism. June 16, 1888

8,871. J. I. RYDER. Matlock, Bath. Improvements in electrical switches, commonly called electrical bell pushes or presses. June 11, 1888.

8,905. H. LAHOUSSE and Co. and C. COLLÉ, of the said firm. London. Improvements in electric batteries. June 18, 1888.

8,912. H. RAISON. London. An electric meter for registering or recording electricity. June 18, 1888.

8,919. J. G. LORRAIN. London. A new or improved type of electric cable, specially applicable for high-tension alternating currents and methods of, and apparatus for, manufacturing the same (La Société d'Exploitation des Câbles Electriques, Système Berthoud-Borel et Compagnie, Switzerland). June 18, 1888.

8,920. J. G. LORRAIN. London. A new or improved type of electric cable, specially applicable to long distance underground and submarine telephony (La Société d'Exploitation des Câbles Electriques, Système Berthoud-Borel et Compagnie, Switzerland). June 18, 1888.

8,950. C. B. BURDON. Birkenhead. Improvements in applying electric traction to pleasure, sporting and business purposes. June 19, 1888.

8,966. E. HOPKINSON and D. APPLETON. London. Improvements connected with or applicable to baths or vessels containing liquids used in electro-plating or dying, or the electrolyte of storage batteries and the like. June 19, 1888.

9,005. F. WYNNE. London. Improvements in dynamo-electric machines. June 20, 1888.

9,032 W. R. MORTIMER and J. HOLLOWAY. London. Improvements in electric arc lamps. June 20, 1888.

9,046. E. COX-WALKER and A. A. C. SWINTON. London. Improvements in magneto-electric bells. June 21, 1888.

COMPLETE SPECIFICATIONS ACCEPTED.

NOTE.—*All persons interested in opposing the grant of a patent on any one of the undermentioned applications may, at any time within two months from the dates in italics, give notice at the Patent Office in the prescribed form of such opposition.*

June 23, 1888.

10,177. E. L MAYER and H. LIEPMANN. London. Improvements in the manufacture or treatment of porous pots, plates or partitions for electric batteries. July 20, 1887.

11,235. R. HANNAN. London. Improvements in the manufacture of rubber composition strips used in the manufacture of insulated wires and cables (J. J. C. Smith, United States). August 18, 1887.

11,390. J. S. STEVENSON. London. Improvements in the manufacture of elements or plates for secondary batteries or electrical accumulators. August 20, 1887.

11,417. T. A. GARRETT. London. Improvements in and connected with electrical connections with moving bodies. August 22, 1887.

11,502. E. H. H. LAUCKERT. London. Improvements in dynamo-electric and electro-dynamic machines. August 23, 1887.

7,536. B. WILLCOX. London. Improvements in galvanic batteries (T. P. Whittier, United States). May 22, 1888.

PATENTS SEALED.

June 22, 1888.

6,221. A. SHIPPEY (London) and W. J. L. HAMILTON (Herne). A mode of and apparatus for governing or regulating by electro-chemical action applicable to the regulation of motors and of the feed of arc lamps and for other regulating purposes. April 28, 1887.

6,581. E MANVILLE and W. S. MADGEN. London. Improvements in holders for electric lamps. May 4, 1887.

7,265. C. ADER. Paris. Method and apparatus for phonic reception of electrical signals. May 18, 1887.

9,853. H. WATT. London. Improvements relating to dynamo-electric machines. July 13, 1887.

COMPANIES' MEETINGS & REPORTS.

London Platino-Brazilian Telegraph Company (Limited).

A general meeting of the shareholders of this Company was held yesterday (Thursday) at Winchester House, Old Broad-street, for the purpose of electing new Directors. In the absence of Sir John Pender, K.C.M.G., who was detained elsewhere, the chair was taken by Capt. Francis Pavy.

The SECRETARY (Mr. William Payton) read the notice convening the meeting, the following being an abstract of the circular:—"The arrangements made by the provisional agreement, dated the 18th day of April, 1888, for the exchange of shares of this Company for shares in the Western and Brazilian Telegraph Company (Limited) (which agreement, as you are aware, has been approved of by special resolution of the shareholders of this Company, passed and confirmed at extraordinary general meetings held respectively on the 27th day of April and the 15th day of May last), have been now practically completed by the shares of the assenting members of this Company being exchanged for shares in the Western Brazilian Telegraph Company, in accordance with the provisions of the above-mentioned agreement. It has therefore now become necessary that new Directors should be appointed in lieu of the present Directors, who are retiring under the provisions of the agreement."

At the request of the Chairman, the Secretary afterwards read the minutes of the last meeting, which were approved by the present meeting and signed by the Chairman.

The CHAIRMAN then said: I need not keep you more than one or two minutes, but there are one or two facts that may be interesting to you. The agreements between the two companies have been carried into effect, and out of the 38,348 shares forming the Platino capital, 33,515 shares have been exchanged for Western and Brazilian Shares, or 4,000 shares beyond the three-fourths requisite to give effect to the agreements. The agreements have been duly registered and lodged at Somerset House, so that matters are now in order, and the exchange virtually completed. It is entirely so so far as the present Directors are concerned. The number of our English shareholders was 345, holding 35,050 shares. Of these 326 shareholders, holding 33,515 shares, have accepted Western and Brazilian shares, leaving 19 shareholders, representing 1,535 shares only. These shareholders are unaccounted for; but these gentlemen have all, save absentees and executors (with one solitary exception of five shares) intimated acceptance of the terms, and will carry them out. As regards the foreign shareholders, there are at Rio 3, at Buenos Ayres 32, and at Montevideo 9. All these we have assurance will concur, with one exception, and that a doubtful one. Under these circumstances, having carried out the agreements, it is now only left, according to arrangement, for the present Directors to resign, and to appoint others in our stead. The solicitors of both companies agree that the best and legal way will be the passing of the resolution which I will now read to you:—

"*The present Directors, viz., Sir John Pender, K.C.M.G., Captain Francis Pavy, and John Hollocombe, Esq., having laid before this meeting resignations of their positions as Directors of this Company, in pursuance of the provisions of the recent agreement of the 18th day of April, 1888, resolved that their resignations be accepted, and that the following gentlemen be and are hereby appointed Directors of this Company, with the positions mentioned below:—W. S. Andrews, Esq., Director; Lord Richard Howe Browne, Director; C. W. Earle, Esq., Director; D. W. Goodsall, Esq., Director; H. Weaver, Esq., Director; and Major Wood, Director.*"

Mr. JOHN HOLLOCOMBE seconded the motion.

The CHAIRMAN; If no one has anything to say, I will put that resolution to the meeting. No shareholder rising to address the meeting, the motion was accordingly put and carried unanimously, the Chairman adding that that closed the business.

Mr. KENNETH ANDERSON, as an old Platino shareholder, said he desired to propose a vote of thanks to the retiring Chairman and Directors of the Company for the skilful and close attention which they had always given to the affairs of the Company. The shareholders all remembered that some time ago the Company was in a very bad plight, but the old Board brought it through its difficulties, and made it a living concern. They must also thank those gentlemen for the skill they had displayed in making the late arrangement, which would enable the shareholders to look forward, under the fostering care of the Western and Brazilian Company, to a bright future.

A SHAREHOLDER briefly seconded the motion.

Mr. W. GRIFFITH: Now that our old Directors have retired and new ones have been appointed, I hardly know to whom I ought to address myself, but probably to the new ones. Under the old *régime* there were some accounts outstanding between the two Boards. The London-Platino entered certain claims for large amounts, which were disputed. Will you kindly tell me what will be the future of those claims—whether they are admitted or still disputed, or in what way they will be arranged?

The CHAIRMAN: First of all I will thank Mr. Anderson for his kind remarks. As it happened, a legacy of a lot of these shares came many years ago into the hands of the Company I am connected with, and we found them of very little value. Aided by the staff, we have worked very hard—nobody knows that better than Major Wood—to get matters into shape, and I think that that is the position now. It has been to our interest to make these arrangements, and I am glad to think that it has been to the interest of the shareholders also. I think I must leave the new Directors to answer the question of Mr. Griffith. The matter is now out of our hands.

Mr. GRIFFITH: It is not yet settled?

The CHAIRMAN: The Company exists as it was, only that it is in fresh hands.

The proceedings then terminated.

The Pilsen-Joel and General Electric Light Company (Limited).

An extraordinary general meeting of this Company was held on Wednesday at the Cannon-street Hotel, Sir Rawson Rawson in the chair.

Mr. W. H. TRENTHAM (the Secretary) read the notice convening the meeting, and also the following requisition to the Directors:—

"We the undersigned shareholders of the Company hereby make a requisition that you convene an extraordinary general meeting of the Company, with the object of proposing to such meeting the following resolutions:—That the instructions to the Directors to sell the property, goodwill, &c., of the Company, given at the meeting held on the 13th of April, 1888, be and the same are hereby adopted, and the Board are instructed to advertise for sealed tenders within a week from this date, for the purchase of the same. That a committee of three shareholders is hereby appointed to act with the Directors in advertising for and in receiving and considering the tenders sent in for such purchase, and to report to the shareholders thereon. That this meeting views with surprise the action of the Directors in making a call of 3s. a share after what passed at the meeting on 13th April, 1888. Dated this 23rd day of May, 1888. Frederick S. Phillips, J. Eglinton A. Gwynne, Andrew Hutton, Arthur P. Blathwayt, Chas. T. D. Crews, Thomas Davis, W. Ellis Willes, James Fyfe, Edwin Gerard, James Gibberd."

The CHAIRMAN said: Well, gentlemen, I have now to proceed to inform you what action we have taken on the resolution passed at the meeting of the 13th April. Our original proposition was made in our notice for the first meeting on the 23rd March, and was, first, that the Directors, with the power vested in them, should make a call of 5s. a share for the purpose of meeting the existing liabilities of the Company and extending installations from their two stations, and in order that the shareholders might divide the profits from such extension, that the nominal capital of the Company should be reduced to the minimum. A small sum was left of £527, simply to make the reduction an even sum for simplicity of calculation. That is the explanation of our not sweeping it away altogether. Well, it was evident at the two meetings that our shareholders were not disposed to advance further capital for the purpose of extending the business, and that was made very clear to us. I had apprised the shareholders in my circular letter of March that the committee that examined into our affairs had stated very clearly that it was indispensable to obtain money to carry on the affairs and to meet the liabilities of the Company, even without any extension. We were as desirous as any shareholder who attended at the last meeting to carry out the views of that meeting, if it appeared likely it would be confirmed at a meeting which it would have been necessary for us to call in order to proceed legally with any action upon the recommendation, direction, instruction, or whatever you like to call it, of the last meeting. The shareholders in general were of course entitled, not only those who were present but all the shareholders were entitled, to know what we were going to do in their interest, and therefore it was absolutely necessary that we should call another meeting to confirm the proposal or direction passed at the last meeting. The Directors, myself and colleagues who were re-elected at the last meeting, were under a very firm conviction that the shareholders in general were not disposed to put an end to the Company; that there were many of them who were more disposed to carry on and to await better times for realising our business, and to obtain some return for the money that has been expended. When that resolution was passed three alternatives presented themselves to the Directors—one, to adopt the view of the last meeting, which was to get rid of the business as fast as possible; the other, to adopt the view advocated, and which we believed a number of our shareholders were disposed to advocate—viz., to carry on and to extend our installations gradually, or to devise some other course which might reconcile the views of the two divisions of our shareholders. Well, when the Board met within about a week of our meeting we found ourselves in this position—that the proceedings at that meeting had become known to parties who had claims upon the company, and who were not only prepared to, but actually did, without giving us a chance of meeting them, take legal proceedings against us. As you are aware our balance at the bank was reduced to the smallest sum; our rentals from installations would not come in for another month, and we were under an obligation to meet our liabilities. Therefore we had no option in the matter; we could not obtain

Digitized by Google

the necessary funds without making a call or pledging ourselves—in fact, a pledge to make a call was not sufficient—we could only obtain money by making a call, therefore we were hurried into that necessity, from no action of our own, and certainly from no indisposition to come to an arrangement, had it been possible, by which we could have avoided a call. We found ourselves, therefore, under the necessity of reconsidering our position with regard to the future. Should we maintain our own view of continuing the business, and what we believed to be the view of the influential body of shareholders to continue business, or should we adopt the view of those who carried the motion at the last meeting to proceed to a sale of the business as speedily as possible? The Directors determined to adopt the latter view, and to act entirely according to the desire expressed by the meeting, the difference being that many who voted for that instruction did so in the expectation that there would be no necessity for making a call; but that necessity was forced upon us, we could not avoid it. Therefore the Directors proceeded in the manner which they considered most desirable. There was a disposition expressed by some shareholders to advertise for the sale of the business. The Directors did not consider that in the position of the Company at that time that that was an eligible course. They thought that it was injurious to the interests of the Company; that it would damage the value of their property by adopting such a course, more particularly after the publication of the proceedings at the last meeting. We therefore, acting upon the instruction, which was to consider the best means of disposing of the business—those were the terms—proceeded to enter into those negotiations with those parties who were likely to take the business off their own hands, and to endeavour to effect an arrangement with them. That has been proceeded with, and that has delayed our calling you together to a certain extent, for the negotiations have been continued up to the latest date; but we believe that we have the opportunity of laying before you a proposal which will realise the value of our assets at the present time, obtain as full a value for them as we can get, release our shareholders from any future obligation with regard to calls, and so far meet what we believe to be the wishes of the majority of the shareholders. One of my colleagues will lay this matter before you. I wish to say that I myself have not interfered in this matter at all, inasmuch as it was supposed by some, or suggested, that my judgment might be interested in this matter on account of my son's connection with a firm; therefore I have taken no part whatever in this matter of negotiation. My colleagues have dealt with it, and one of them will explain to you his proceedings. The other point that I have to bring before you is the question of the amount of the call. We originally proposed 5s., with a view of meeting our liabilities, of extending our installations, but when it was obvious that our shareholders were not disposed to carry on the business and desired it to be wound up as speedily as possible, and, of course, with as little expense to themselves as possible, we had to consider what amount would be required to meet the three distinct objects. One was to cover all liabilities existing or likely to accrue from the state of things as it existed at the moment, the other was to provide for a quarter's maintenance of our installations, because we have to furnish our customers for a quarter at least before they pay for them, and we were bound to consider the interest of our customers, in which our own interest was closely bound up in this matter. Then another point was to raise such an amount as would render it absolutely certain that we should not be required, or that any parties taking over the business from us should have to make another call for a small balance. It would have been a very unwise thing for us to make a 2s. call or a 2s. 6d. call if it was likely or possible that we should then have to make another call of 6d. or 1s.; therefore, inasmuch as we should not expend any more of this money than was absolutely necessary, we made a call of 3s. instead of 5s., which would render it certain we should have sufficient to wind up the business, which might take weeks, perhaps many weeks, before we might get a satisfactory offer and come to a final settlement. With regard to the negotiations, I will ask Mr. Whateley, who has been good enough to undertake them, to state what has been done; but I should like to mention what has been the result of our inquiries and the information that has come to me as to the difficulties that this matter presents. With regard to our business, one of our difficulties is that all our arrangements are annual, our contracts with our customers are annual. That affects very much the value of our assets, because it is in the power of those parties to withdraw, and therefore there is an uncertainty respecting the arrangement. Another objection that we have met with is in regard to our plant, that it is not of the latest type, and that it has been improved upon. That is one difficulty. Then with regard to patents, that has been another difficulty. Most of the parties who are lighting in London and elsewhere have their own lamps and patents, and are not disposed to pay for patents for another lamp when they are satisfied with their own or other lamps which are in the market. These are difficulties with which the negotiations have been met. I trust that Mr. Whateley will explain to you our position, which, as I understand it, is one that will be satisfactory to the shareholders generally. I will read the resolution, which the Board has only within the last day or two felt itself in a position to submit. We hope that it will meet your views; at any rate, it will show that we are anxious to meet the views expressed on the last occasion, and I think it will meet the views of the majority of those who are present here to-day. I move

"*That the instructions to the Directors to sell the property, goodwill, and assets of the Company, given at the general meeting held on the 13th April last, be and the same are hereby adopted, and that the Directors be and are hereby authorised to accept payment in cash or fully-paid-up shares of any other company, or partly in cash and partly in such shares as may be arranged, and that a committee of three gentlemen are hereby appointed a committee to consult with and assist the Directors in negotiating for such sale.*"

We are most anxious that the shareholders shall have the fullest security that in any arrangement entered into their interests will be looked after to the fullest extent.

Mr. FELLOWES thought it was not competent to the meeting to consider any such resolution. The resolution passed at the last meeting was *ultra vires*. He thought that they should consider whether the business could be carried on.

Mr. D. PARRISH said that the Directors had acted under legal advice. He understood that the Directors had done their best to sell the business.

Mr. WHATELEY said that when the Board came to the decision, which they did after a great deal of consultation, as to whether it would be better to sell by tender or not, they came to the decision that to offer the affair by tender would be practically selling all their plant for next to nothing. He was told by gentlemen that their plant was not of the most modern type; he did not believe it was, because the bulk of it was made some time ago. The first people he approached was the Grosvenor Gallery, who were doing as much as anybody in the electric lighting way; they positively declined to have anything to do with the Company, on the ground that their plant was out of date. They had also been to the House-to-House Electric Company and to the Anglo-Brush Corporation. They had also had some communication with Mr. Crompton and the Kensington Court Company, but there had been no result. They next put themselves in communication with Woodhouse and Rawson, who took an immense deal of trouble in the matter. He had had several interviews with the head of the firm, Mr. Foot, who proposed to start a syndicate company with £50,000 capital; they proposed to give this Company a fifth of the share capital, and when the syndicate sold the undertaking to a company they were to have a fifth of the proceeds in cash and shares besides a certain royalty on patents they possessed. The Directors would be very glad of the assistance of shareholders to carry out this arrangement.

Mr. JAS. FYFE said that he had signed the requisition for a sale under supervision as the lesser of two evils under the then existing circumstances. The Directors had been instructed by a meeting—which restored them to power for that sole purpose—to sell the business, and he opposed both their restoration to power and the sale at that meeting, as he considered neither was for the benefit of the shareholders. The Directors had also expressly withdrawn at that meeting their announced intention of making the call they were proposing of 5s. The report of the Committee of Investigation was only not read at that meeting for the reason that the majority then present of the shareholders, as they were deciding upon a sale, considered it unnecessary to have a discussion upon the report, disclosing as it did the gross mismanagement of the Directors; but to avoid this discussion a vote of thanks to the committee who had prepared the report was suggested by one of the Directors themselves, and unanimously carried—and to this day the expenses of that report had not yet been paid by the Company. That was the position of matters after the last meeting. But what do the Directors do upon this? Practically they say, "*You have put us back into power formally; we have succeeded in getting the report burked*—but the sole condition and reason for both these facts, viz., that we should sell the business was informally *carried*, and we will ignore it and continue our management," which every shareholder must condemn, and which as stated in the report has received the most emphatic condemnation by the leading papers of the electrical press, who only refrain from still further condemnation because they await what they assume will necessarily follow. He considered that any course would be better than continuing the business under this management, which had in four years worked so much harm—had been doing a largely-decreasing business year by year with an annual increase of expenditure—and, in addition, had in eighteen months squandered about £4,000 invested moneys of the Company. He accordingly joined with other shareholders in a requisition to the Directors to call a meeting, to make that formal which they said was informal, viz., the resolution for sale This was disregarded by the Directors upon a pitiful technical objection they raised, that they had been by the requisition asked to call the meeting for a particular day, to which day they could not suggest any objection however. We were, therefore, put to the trouble of sending another requisition, upon which the present meeting is called. And how do the Directors meet us when they are at last reluctantly forced to do so? Why they say they have been privately negotiating for a sale of the business, which is what they were asked not to do, and they say it has been proposed to them by one shareholder that the Directors who had been acting for a year and a-half improperly—the very year and a-half in which the invested £4,000 Consols were squandered—should have a sum of money voted to them for this signal service to the Company. What they did besides this I know not, because having examined the minute book of this period I find a dreary monotony of the proceedings of each meeting (recorded by themselves, be it remembered) of—"Present the three Directors. Cheques signed for so and so." Nothing else; no business done, or even discussed or considered, only signing cheques—so long as the money lasted. And it will not be forgotten that when the Committee of Investigation commenced its labours there was absolutely not one farthing in the bank. But the real practical question is as to the future of the Company, and as to the policy to be pursued. If the business were to be sold, what is likely to be realised for a business which has been allowed to run four years practically without any profit, which has been so publicly discredited as this has been by its Directors, who issue their circular that its goodwill and patents, lately valued by themselves at £25,000, are now worth only £500? The effect of this sale would be that since the last meeting the Directors have called up further capital of about £3,600 to enable them to sell for about that amount. But I do think it is not in the interests of the general body of shareholders of the Company that there should be a sale at all. Here is a property, the mere goodwill and patents of which were valued last year, and I think moderately, at £25,000, which admittedly is earning even under the present utterly inefficient management over £5,000 per annum from customers of undeniable responsibility, which has central

Digitized by Google

lighting stations of almost unique advantages in the electric lighting business, capable of practically unlimited extension for further customers whom the present Directors will not even supply when brought to them, and this at a comparatively trifling outlay. The lamp is admittedly the best arc lamp in the market. The Company have the patents for India, Australia, and Canada, in addition to the patents for the United Kingdom, none of which have been worked or sought to be worked in any part of these territories, during the existence of the present directorate, except England, a full working stock and plant, valued by your committee at £10,000 and upwards, and all these are to be put into the market and thrown away for what anyone will give for it, merely because the Company have been afflicted with a Board of Directors who have grossly mismanaged their business, and who have not in their conduct of it been governed by the most ordinary business principles, or shown any regard for either efficiency or economy. Now, I do not know why the Pilsen Company's business should be dealt with upon any other lines than any other business; and if another business known to be good was managed by persons known to be bad, the owner would, in the ordinary way I suppose, not sell his good business, but dismiss his bad manager. I must say that I think this is the true solution of the difficulty. Invite the Directors to resign the positions in which they can no longer possess the confidence of the shareholders, select at a future meeting three business men from among the body of shareholders to conduct the business of the Company, and I will confidently predict that this company will be as prosperous in the near, if not the immediate, future as it has been unprofitable and almost disastrous in the past. Firmly believing this, and that any sale would be a most mistaken policy, I beg to move the following amendment to the resolutions:—"*That in the opinion of this meeting any sale of the Company's business at the present time is inexpedient; that the proposal to make a payment to the Directors for acting as they did whilst disqualified be not entertained; that the present Directors be requested to resign; and that the Secretary is hereby directed forthwith to convene a meeting of shareholders to elect other Directors.*"

Mr. GWYNNE said that the Company had been mismanaged from the commencement, and moved an amendment in accordance with the terms of the requisition.

After some further discussion, both the resolution and amendment were withdrawn, and on the motion of the CHAIRMAN, seconded by Mr. SCRIVEN, the following resolution was agreed to, viz.:—

"*That the Directors be instructed to consider the best means of disposing of the property, goodwill, &c., of the Company, or, in the alternative, to consider the advisability of carrying on the business, and that the Board be instructed, if a sale be determined upon, to advertise for sealed tenders for the purchase of the business, or to make such other arrangements for the disposal of the business and assets as they and the committee hereinafter named may think fit; that Messrs Phillips, Guynne, D. Parrish, and Fyfe be and are hereby appointed the committee, to act with the Directors in arranging and negotiating such sale subject to the consent of the shareholders being obtained before any proposal for the purchase is finally accepted, or any arrangement for carrying on the business is made.*"

The proceedings then terminated.

The South of England Telephone Company.

Report of the Directors for the year ended 30th April, 1888, to be presented at the fifth ordinary general meeting of the Company, to be held on Friday, the 29th inst., at Winchester House, 50, Old Broad-street, E.C., at 1 o'clock:—

The expenditure on capital account during the past year amounts to £16,457. 6s. 9d., bringing the total of that account to £44,384. 6s. 8d.

The revenue account shows a sum of £12,354. 10s. for subscriptions and rentals, and a net credit balance of £3,905. 12s. 2d., making, with the sum of £1,058. 9s. brought forward from last year, an available balance of £4,964. 1s. 2d.

After providing for the Preference dividends (£1,849. 0s. 6d.), which have been paid, a balance of £3,115. 0s. 8d. remains, out of which the Directors recommend the payment of a dividend on the Ordinary shares at the rate of ½ per cent. for the year, free of income-tax, which will absorb the sum of £1,500. The Directors also recommend the transfer of £500 from the revenue balance to a reserve fund account, in order to commence this fund—as suggested by the auditors—leaving a balance of £1,115. 0s. 8d. to be carried forward.

The completed trunk lines are as follows:—

Brighton—Shoreham.	Dover—Folkestone.
Brighton—Worthing.	Chatham—Maidstone.
Brighton—Lewes.	Norwich—Great Yarmouth.
Margate—Ramsgate.	Northampton—Wellingboro'.

The trunk lines in process of construction are—

Canterbury—Dover.	Lewes—Eastbourne.
Canterbury—Ramsgate.	Wellingboro'—Kettering.
Canterbury—Deal.	

At the 30th April, this year, 1,435 exchange lines and 373 private lines were completed; and 86 exchange lines and 13 private lines were in course of construction.

Telephone exchanges are now open at the following places:—

Brighton	Hastings and St. Leonards	Oxford
Cambridge	Ipswich	Peterborough
Canterbury	King's Lynn	Ramsgate
Chatham	Lewes	Reading
Dover	Maidstone	Shoreham
Eastbourne	Margate	Tunbridge Wells
Folkestone	Northampton	Wellingboro'
Great Yarmouth	Norwich	Worthing

Mr. T. F. Campbell retires from the Board by rotation, and, being eligible, offers himself for re-election.

The shareholders' auditor, Mr. J. Weise, retires, and is eligible for re-election.

United Telephone Company (Limited).

The following is the report of the Directors for the year ended 30th of April last, to be presented to the shareholders at the eighth annual ordinary general meeting of the Company, to be held at the Cannon-street Hotel, on Tuesday, the 3rd prox.:—

Capital Expenditure.—A reference to the capital account will show that up to the 30th April, 1888, the sum of £263,876. 10s. 10d. has been expended upon the works in connection with the Metropolitan District and instruments on royalty in the Metropolitan District and subsidiary companies, being £35,695. 18s. 8d. more than the outlay shown in the last balance-sheet.

Revenue.—The revenue accounts, exclusive of Metropolitan District royalties, show that the receipts of the Company from all sources properly attributable to the year have been £143,134. 18s. 5d., as against £130,704. 7s. 5d. in the preceding year, or an increase of £12,430. 11s., and the expenditure (including snowstorm losses and allowances,

£15,653. 8s. 7d.) has been £73,519. 8s. 8d., as against £66,954. 11s. 8d., or an increase of £6,564. 17s.

Working Expenses.—(*Metropolitan District.*)—The working expenses for the year have been £35,724. 12s., as against £30,483. 14s. 2d. for the preceding year, or an increase of £5,240. 17s. 10d.

Dividend.—The balance of net revenue account is £68,697. 4s. 1d., of which amount the sum of £22,377.15s. has been absorbed by the payment of an interim dividend at the rate of 10 per cent. per annum for the first half-year ended 31st October, 1887, and the Directors recommend a further dividend of 10s. per fully paid £5 share and 5s. per part paid share for the second half-year ended 30th April, 1888, amounting to £44,755. 10s., making a total dividend of 15 per cent. for the year, leaving a balance of £1,563. 19s. 1d. to be carried forward.

Reserve Account.—A sum of £14,375, being the amount received during the year as premium on new shares, has been carried direct to the reserve fund.

Directors.—It is with the greatest regret that the Directors have to refer to the decease of the late Mr. E. Dwyer Gray, M.P. To fill the vacancy thus occasioned they have, subject to confirmation by the shareholders, elected Mr. Frederick R. Leyland to a seat on the Board. Mr. John W. Batten and Mr. Frederick R. Leyland retire by rotation, and, being eligible, offer themselves for re-election.

Auditors.—The auditors, Messrs. Quilter, Welton and Co., and Messrs. Price, Waterhouse and Co., also retire.

NEW COMPANIES REGISTERED.

J. AND J. CHARLESWORTH (LIMITED).—This company proposes to take over the business of Messrs. J. J. Charlesworth, colliery owners, &c., carried on at Lofthouse, near Wakefield. Power is also taken to carry on business as electricians and mechanical engineers. It was registered on the 14th inst., with a capital of £500,000, in £100 shares, the following being the first subscribers:—

	Shares.
*A. H. Charlesworth, Chapelthorpe, colliery owner	1
*J. B. Charlesworth, Wakefield, colliery owner	1
Mrs. E. B. Charlesworth, Wakefield	1
*J. Charlesworth, Lofthouse, Wakefield, colliery owner	1
*C. E. Charlesworth, Doncaster, colliery owner	1
Mrs. F. Charlesworth, Doncaster	1
Mrs. E. G. Charlesworth, Wakefield	1

The number of directors is not to be less than 3, nor more than 5; qualification, £10,000 in shares or stock. The first are the subscribers denoted by an asterisk; remuneration, £2,000 per annum.

THE INTERNATIONAL ENGINEERING COMPANY (LIMITED).—Registered by Nores and Pattison, 52, Lincoln's Inn-fields, W.C. Capital £5,000, divided into 5,000 shares of £1 each. Object, to purchase or acquire certain inventions relating to electric motors, and to means for carrying electrical batteries for driving tramway vehicles and for other purposes, invented by William Denton Sandwell; to construct, equip and work light railways, tramways, ships, lines of telegraph, telephone, &c., and to carry on business as manufacturers and suppliers of electrical, steam, or other mechanical or animal or other motive power or electricity or light. The first subscribers are:—

	Shares.
J. Drage, clerk, 26, Osborne-terrace, Clapham-road, S.W.	1
E. A. Rider, clerk, 8, Lugard-road, Queen's-rd., Peckham, S.E.	1
W. B. Pattison, solicitor, 52, Lincoln's Inn-fields, W.C.	1
J. H. Yates, teacher of music, 63, Frith-street, W.	1
C. Wickison, housekeeper, 52, Lincoln's Inn fields	1
J. L. Hofman, clerk, Warwick-road, New Barnet	1
W. Davis, shorthand writer, 420, Edgware-road, N.W.	1

There shall not be less than three nor more than seven directors, and the first shall be elected by the subscribers to the Memorandum of Association. The qualification shall be the holding of not less than £100 in the capital of the company. Remuneration of directors is not stated.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended June 22nd, 1888, were £4,072.

EASTERN AND SOUTH AFRICAN TELEGRAPH COMPANY.—The directors of this company notify that the coupons, due July 2, on their Five per Cent. Mortgage Debentures will be paid on and after that date at the banking-house of Messrs. Barclay, Bevan and Co., 54, Lombard-street, E.C.

MANITOBA ELECTRIC AND GAS LIGHT COMPANY OF CANADA.—Messrs. Robert A. M'Lean and Co. will pay, on and after July 1, the half-yearly interest coupon on the First Mortgage Six per Cent. Bonds for £62,000 of this company.

TELEPHONE COMPANY OF AUSTRIA.—The directors of this company notify that coupon No. 7 of their Five per Cent. Debentures, due July 1 next, will be paid, less income-tax, on and after July 2, by Messrs. Martin and Co., 68, Lombard-street.

WEST COAST OF AMERICA TELEGRAPH COMPANY.—The coupons due the 30th inst. on the debentures of this company will be paid by Messrs. Barclay, Bevan and Co. The coupons must be left three clear days for examination.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended June 22nd, 1888, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,385.

CRICKET.

EASTERN TELEGRAPH COMPANY v. SUBMARINE TELEGRAPH COMPANY.

This annual match was played at Nunhead on Saturday last, and was favoured with splendid weather. The Eastern Company won the toss, and decided to go in, Messrs. Seymour Wells and M'Millan taking the bat. Both gentlemen batted well, and made 49 runs before the latter was caught for a very useful 29. Mr. Wells's batting was remarkably steady, and his wicket-keeping deserves special mention. The Submarine could make no stand against the excellent bowling of the Eastern. Mr. M'Millan baffled the batsmen completely, taking four wickets at a cost of only three runs. Mr. A. Jack captained the Eastern Eleven, and Mr. Collard that of the Submarine Company. Messrs. Shanks and Gregory were the umpires. Score:—

EASTERN COMPANY:—Mr. M'Millan, c Breedon, b J. Spicer, 29; Mr. Seymour Wells, c Cross, b Robinson, 36; Mr. Chisholm, run out, 14; Mr. A. Jack, b Cooper, 18; Mr. Couper, b Cooper, 10; Mr. W. Macdonald, b Breedon, 4; Mr. Richardson, b Cooper, 2; Mr. R. Donaldson, c Collard, b Breedon, 12; Mr. Grigor, c Cooper, b Breedon, 0; Mr. W. Donaldson, not out, 2; Mr. J. White, absent, —; Byes 10, leg byes 3, no ball 1, 14. —Total, 141.

SUBMARINE COMPANY:—Mr. Breedon, c Chisholm, b M'Millan, 1; Mr. Cross, run out, 4; Mr. Wright, b M'Millan, 0; Mr. Collard, b Chisholm, 9; Mr. Muzio, run out, 0; Mr. Cooper, b Chisholm, 7; Mr. Robinson, b M'Millan, 0; Mr. Robinson, b Chisholm, 0; Mr. J. Spicer, b M'Millan, 3; Mr. Gee, run out, 0? Mr. R. Spicer, not out, 0; Byes 7.—Total, 31.

Dr. GASSNER'S PATENT **BRY BATTERY** Dr. GASSNER'S PATENT

FOR

TELEGRAPHIC WORK, ELECTRIC BELLS, AND MEDICAL USE.

Possesses all the advantages of a Leclanché Cell, and none of its deficiencies.

Sole wholesale depot for England,

MAYFIELD, COBB & CO., LTD., 35a, QUEEN VICTORIA STREET, LONDON, E.C.

THE NEW BURGLAR ALARM CONTACT (Patent applied for); cannot get out of Order. Rubbing Contact, and Wetproof.

THE NEW INDICATOR MOVEMENT (Patent applied for). Simplicity and Efficiency.

Trade Terms and particulars on application to MAYFIELD, COBB & CO., Limited.

Offices—**WINCHESTER HOUSE, OLD BROAD STREET, LONDON, E.C.**

The principal objects of the Corporation are:—

1. Performing the duties of Trustee, Executor and Administrator.
2. The Insurance of Bonds, Shares and all other Securities lodged with the Corporation against risks of all kinds.
3. The Issue of Warrants and Certificates against Securities deposited, and making and procuring advances on such Warrants.

The Office of Trustee or Executor is to private persons usually a thankless post, involving much anxiety, time and money, and frequently leads to serious actual loss; whilst death, illness and change of residence necessitate frequent fresh appointments, and consequent expense to the parties interested. The Corporation undertakes all the duties of Executor, Trustee or Administrator for reasonable remuneration proportioned to the work and responsibility in each case.

The Corporation insures existing Trustees and Executors against all risks attending those positions, where the business is conducted by the Solicitors to their Trusts under the supervision of the Corporation, it not being the desire of the Corporation to interfere in any way with the duties of the family solicitor.

The Corporation acts as Trustees for the Debenture Holders in Public Companies.

For terms, &c., application should be made to the General Manager at the Company's Office.

GEORGE PEARSON, *General Manager and Secretary.*

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL SCIENCE, INDUSTRY AND ENGINEERING.

No. 529.—Vol. XXI. FRIDAY, JULY 6, 1888. Price 4d.

NOTES.

On Monday morning, after an adjournment of four weeks' duration, Mr. Justice Kay once more resumed the hearing of "Edison and Swan Electric Light Company *v.* Holland and others." The learned judge had already for some days been in possession of the report drawn up by Prof. Stokes, P.R.S., upon the experiments carried out in his presence by experts on either side. This report was not read in court, but the full text will be found in our present issue. To the satisfaction, we presume, of nearly everyone concerned, great and unexpected progress has now been made. The speeches of counsel, instead of extending over several days (as was fully anticipated) were concluded in as many hours, and we have now only to await the judgment.

The case of Gaulard and Gibbs *v.* Ferranti, which is now occupying the attention of Mr. Justice Kekewich in the Court of Chancery, requires, perhaps, a few words of explanation as regards the legal status of the parties to the suit. Notwithstanding that Messrs. Gaulard and Gibbs figure as plaintiffs, the suit is really initiated by Mr. Ferranti, who has filed a petition in the Court of Chancery for the revocation and annulment of Patent No. 4,362 of 1882, of Messrs. Gaulard and Gibbs, on the ground mainly of want of novelty in the subject matter, and also of a lack of utility. When a suit of this character comes before the Court the patentees possess the right to open the case, and hence, for the sake of convenience, they are distinguished as the plaintiffs and the petitioner becomes the defendant. Meanwhile we are informed that Messrs. Gaulard and Gibbs have instituted proceedings against Mr. Ferranti and the Grosvenor Gallery Company for infringement of their patents. We take it, however, that the issue of the present trial will virtually decide the cross-action also. It may be as well to explain, further, that since the commencement of the present suit Messrs. Gaulard and Gibbs have obtained the permission of the Controller of Patents to amend their original specification. In another column we print the specification, showing the difference between the original and the amended form upon which the case is being fought out.

Owing to the sudden interruption of both the Java-Port Darwin cables on 30th June, Australia is temporarily cut off from telegraphic communication with this country. The Eastern Extension Company's repairing vessel "Recorder" is now at the position of the break, and it is expected that repairs will be effected quickly. Below we give some particulars of previous interruptions to the communication, in order to correct inaccurate statements which have been made public. Direct telegraphic communication between England and the Australian Colonies was established in October, 1872, and from that date until 1880, when the company duplicated their system between India and Australia, the cable service to Port Darwin (Northern Territory of South Australia) was only totally interrupted on two occasions, viz., in 1877 for 38 days, and in 1879 for 18 days. Since the duplication of these cables in 1880, telegraphic communication has only twice been interrupted for an aggregate period of 13 days. The South Australian land line between Adelaide and Port Darwin has been interrupted from time to time, but the interruptions have seldom lasted for many hours, the longest on record not exceeding five days.

In order to provide as far as possible against a similar interruption the company have promptly decided to lay immediately another cable between Banjowanjie and Beagle Bay, Western Australia. The breakage of the existing cables was apparently due to some convulsion at a depth exceeding 1,000 fathoms, and is another illustration of the difficulties which have to be encountered by the comparatively new enterprise of cable-laying and repairing in deep seas. The Eastern Telegraph Company had a similar experience three years ago, about 140 miles from Aden, when both of their cables broke in the same neighbourhood in 800 fathoms of water during a cyclone. The Eastern and South African Telegraph Company had a singular experience with their section between Zanzibar and Mozambique. For five consecutive years the cable broke in the same locality off the Rovuma River, all the interruptions occurring in the months of March or April. Elaborate soundings were taken but no cause for the breakage could be found; and as no better or more regular bottom could be desired, the company resolved to lay a duplicate line far outside the neighbourhood of these breaks; and that being done they shifted the original cable close to the shore, so that they have one cable in very deep and another in very shallow water; and since then, now three years ago, there has been no interruption of any kind. It is hoped the cable companies may some day understand more about these convulsions, and be enabled to lay cables so as to avoid the localities where they occur. It is, however, satisfactory to know that cables can be so readily repaired, even in distant seas, although the companies are obliged at great cost to have tanks with spare cable and repairing steamers available at many points to maintain the great network of submarine lines, which now exceed in length 110,000 nautical miles.

The conditions under which electrolytic decomposition may be effected by an alternating current is a subject upon which very little has hitherto been made known. Considering the very great scientific interest which attaches to the question, in addition to the practical importance which it may possibly assume, it is a little surprising that it should have been neglected for so long a time. In our last issue, however, we gave a translation of a recent Paper by MM. MANEUVRIER and CHAPPUIS, in which certain definite conclusions are set forth; and next week we hope to publish an article on the same subject by Prof. AYRTON. We understand that Prof. AYRTON's investigations have led him to conclusions of a somewhat different character from those arrived at by the French observers.

MEANWHILE, M. NEYRENEUF, writing in the *Journal de Physique*, describes some results of a remarkable character obtained by the use of aluminium electrodes. In a voltameter of this description filled with dilute acid and traversed by an alternating current, the author finds that pure hydrogen is evolved at both electrodes. What becomes of the oxygen we are not told, but no doubt the plates are simultaneously oxidised. When, however, one electrode is of aluminium and the other of mercury, and the liquid is distilled water, much more extraordinary results ensue. *The current passes in one direction only*, and the arrangement forms what the author calls an electric valve. The current which gets through is, moreover, in the reverse direction to that which would be due to the mercury-aluminium couple itself. Furthermore, the addition of some drops of acid to the distilled water notably *diminishes* the current. The aluminium may be replaced by other metals with results of the same general character, but the apparent resistance of the cell is much greater. Nickel and zinc cause the current to pass in the reverse direction. The author does not tell us what relation the phenomenon bears to the E.M.F. of the alternating current, nor does he give any idea as to the E.M.F. employed. These are points upon which we shall hope in due time to receive further information.

THE Electro-Technical Society of Vienna, following the illustrious example of our own Society of Telegraph-Engineers and Electricians, some time ago appointed a special committee to consider what precautions should be taken in the installation of electric lighting plant. The result of the labours of the committee has now been made public, and while the greater part runs upon stereotyped lines to which no exception can be taken, we yet meet with several innovations which will scarcely commend themselves to English electricians. For instance, one of the rules sets forth that the maximum current density in the conductors shall not exceed three amperes per square millimetre (1,875 amperes per sq. in.) for covered wires, while for bare wires a density of four amperes per square millimetre (or 2,500 amperes per sq. in.) is permitted. Since the labours of Prof. FORBES in 1883 we had thought that it had been a matter of common knowledge that a covered wire can take a higher current density than a bare wire of the same diameter for the same rise of temperature. Copper of 80 per cent. conductivity is allowed. The insulation resistance is to be 5,000 times the conductive resistance—an awkward rule for series circuits. When transformers are used the difference of potential at the terminals of the *primary* coils is not to exceed 200 volts; parallel working is therefore ruled out of court. But though 200 volts may be used at the transformers, not more than 150 is permitted at the terminals of the dynamo. In fact, we are afraid that these rules are a sorry jumble; and, seeing that English capital is largely employed on electric lighting enterprise in Austria, it is much to be hoped that no executive authority will attach to them.

ON the subject of capital punishment by electricity an eminent correspondent writes to us from the other side of the Atlantic as follows:—"As an electrician you will be interested in hearing that the State of New York has extended the domain of your science by passing an Act for putting murderers to death by electricity instead of hanging. I think there ought to have been a clause providing that the murderers should put *us* to death by electricity, instead of poisoning us or blowing out our brains."

OUR correspondent's suggestion goes to the root of the matter, just as did Talleyrand's "Let the assassins begin," when he was asked to abolish capital punishment altogether. For offences against society either we have a right to punish or we have not. If we have not, then detention of the offender in safe and pleasant retirement is all that society for its own protection can fairly do in the case. To claim the right to punish and yet shrink from inflicting punishment is at once illogical and effeminate. And if society has grown so squeamish as this, we strongly object to its disagreeable duty being transferred to the shoulders of science. Especially do we object to its being put upon electrical science: first, because electrical science does not lay itself out for the business of capital punishment, and might not succeed at it; secondly, because we do not care to be associated with the vocation of Mr. Jack Ketch; and, lastly, we object from a business point of view to being identified with a transaction so extremely deadly in its operation as capital punishment is, or ought to be.

WE should be sorry to say anything calculated to add to the apprehension which already prevails on the question of a foreign invasion; but, on the other hand, when the question under discussion is one of practibility, as it was in the House of Lords last Friday evening, it is desirable that the actual facts should not be disguised. This Lord SALISBURY assuredly did in respect to the reliance to be placed on the Channel cables in the event of a sudden and secretly planned invasion from the coast of France. If the cables were simultaneously interrupted, says his lordship, we should be warned. Probably; but whether in time is a matter open to dispute. And when he goes on to assert that if they remained intact we should be informed as well as warned the statement is simply absurd. If the French contemplated an invasion we may be perfectly sure they would take timely possession of all the channels of telegraphic communication, and work them to suit the occasion. We did the thing ourselves in Egypt very successfully more than once, and this in a hostile country.

Saigon.—French firms are reminded by the Mayor of Saïgon that tenders have been invited for the electric lighting of that town.

Iron Pipes Melted by Lightning.—During a severe thunderstorm at Lytham a house was struck by lightning, and several iron gas pipes were melted by the discharge.

Gravesend.—The Urban Sanitary Authority of Gravesend are prepared to receive proposals and tenders for lighting the town by electricity. Further particulars may be found in our advertisement columns.

Torgau.—A short time ago the water supply of the town was seriously interfered with owing to a flash of lightning striking a poplar tree near the reservoirs, and on investigation it was found that one of the mains was seriously damaged by the lightning.

Berlin.—A few nights since, owing to the breaking of a cable, all the arc lights supplied from the Friedrichstrasse central station at Berlin were suddenly extinguished. Immediately after the telephone central exchange received 300 calls for communication with the electric light company.

Lighting of Bentley Priory.—The new residence which has just been completed at Bentley Priory is fitted throughout with the electric light. Power is supplied by a Marshall engine and boiler driving an Elwell-Parker dynamo, which supplies current for charging twenty-seven D and G cells.

The Eastern Extension Company's Australian Cables.—The Eastern Extension Telegraph Company notifies the interruption of its two cables between Java and Australia. A repairing steamer leaves Singapore immediately to effect repairs, and it is expected that communication will be restored in about ten days time.

Newton Abbot.—The extensive mills of Messrs. Vicary, tanners, Newton Abbot, have recently been fitted with the electric light. The dynamo, a 100-light machine, is driven by the large engine used for the machinery. There are 82 lights in the mill, 20 of which are of 50 candle-power, and the remainder of 16 candle-power.

Edinburgh.—At the last meeting of the Edinburgh Town Council, in reply to Mr. Ritchie, the Convener of the Streets and Buildings Committee said that any concession the Town Council proposed to give the Anglo-American Brush Company was not in the nature of a monopoly, and would not prevent other electric light companies supplying light in the city.

The Anglo-French Cables.—The *Matin* of July 3rd stated that an agreement between England and France has just been signed for the direct working by the British and French Governments, in joint and mutual account, of the submarine cables uniting the two countries, the arrangement to come into force on January 1st, 1889. The *Matin* adds that the tariff is to be reduced to 20 centimes per word, and that a direct line is to be established between Havre and Liverpool.

The Lighting of the Lower Austria Jubilee Exhibition.—This exhibition, which was opened on the 14th June, covers an area of 87,000 square metres, and is lit by 250 arc lamps and from 2,500 to 3,000 glow lamps. The machine room takes up 2,500 square metres, and contains 15 boilers and 12 engines, giving a total of 1,200 horse-power. There is a considerable variety of plant, the engines and boilers being supplied by 15 different firms, and dynamos by Messrs. Siemens, Gülcher, and Kritzik.

Final Conference on Technical Instruction.—A final conference on technical instruction will be held at the Technical College, Leonard-street, City-road, E.C., on Wednesday, July 11th, at 8 p.m., when Sir Albert K. Rollit, M.P., will preside. This conference is the last of a series of conferences which have been held during the present session. At the former conferences technical education was discussed mainly in relation to the training of artisans in the different trades. At this conference, which will be an open one not restricted to any particular trade or group of trades, discussion will be invited upon the proposals for technical instruction now before Parliament.

London Platino-Brazilian Telegraph Company.—In virtue of an arrangement which is likely to prove very beneficial to the shareholders of this company the management of the concern has been taken over by the Western and Brazilian Telegraph Company. The shares of the former company have been exchanged for those of the latter, and, as a consequence, a formal resolution accepting the resignations of Sir John Pender, Captain Parry, and Mr. John Hollocombe, and appointing as directors Mr. W. S. Andrews, Lord Richard Howe Browne, Mr. C. W. Earle, Mr. D. H. Goodsal, Mr. H. Weaver, and Major Wood was agreed to on the 28th June. A report of the proceedings appeared in our issue of 29th June.

Nottingham.—At the last meeting of the Nottingham Town Council it was stated that letters had been received, addressed to the Urban Sanitary Authority and to the Vestry of Nottingham, from Messrs. W. T. Glover and Co., of Salford, informing those bodies that application was intended to be made on or before the 21st December next, by memorial to the Board of Trade, in pursuance of the Electric Lighting Act of 1882, for a provisional order, to be confirmed in Parliament in the ensuing Session, whereby it was proposed to authorise Messrs. W. T. Glover and Co., or a company to be formed for the purpose of supplying electricity for any purposes within the area of the jurisdiction of the Urban Sanitary Authority or of the Vestry of Nottingham.

Electric Launches at Henley.—The Henley-on-Thames Royal Regatta of 1888 should be historically memorable for the first appearance on this occasion of the electric launch. On Monday Messrs. Immisch and Co's. floating charging station was towed up from Kew, accompanied by the electric launch "Malden," and also the small electric skiff which is used as a tender for the station. From Chiswick to Teddington the towing was effected by the "Malden" herself, which was able to make a good five miles an hour, even with this heavy load. At Henley the charging station is moored nearly opposite the stewards' barge, and after dark an effective display of arc and incandescent lighting is made. We shall have more to say about the "Malden" in an early issue.

New Transformers.—A certain Herr Doubrava, who appears to do business in the neighbourhood of Brünn, Austria, has brought out a new direct-current transformer. There are two conductors, one of small capacity, A, and the other of larger capacity, B. A is first switched on to the mains and charged, and then discharged into B. B is then switched on to the house mains, and A is again recharged, this series of operations being kept going continuously by a small motor actuating the necessary switches, worked from the high potential mains. The same worthy gentleman also expects great efficiency from his alternating-current transformer, in which the high E.M.F. mains are connected to two plates which work inductively on two other plates connected to the house mains. If we mistake not this latter device has already received the protection of the Patent Office in this country, the first true and original inventor thereof hailing from the banks of the Clyde.

The Van Rysselberghe System.—We have already referred to the fact that the Van Rysselberghe system has not given entire satisfaction in Switzerland, and has, indeed, been abandoned on some of the principal lines. (See *The Electrician*, May 18, p. 33.) M. Van Rysselberghe now writes at considerable

Digitized by Google

length in the *Journal Télégraphique*, asserting that he has been sacrificed to the interests of certain financiers. He continues as follows:—"The Lausanne-Geneva and Bâle-Zurich lines were constructed by Messrs. Mourlon and Co., good working being guaranteed, payment only to be made if the system worked to the complete satisfaction of the authorities. Payment has been made, and the goodness of the service has been testified to after several official trials." To this M. Rothen, assistant-director of the Swiss Telegraphs, answers:—"I am authorised to give a formal denial to these assertions. The reasons which led the Department to pay Messrs. Mourlon and Co. without demur, in spite of the usatisfactory working of the lines, are to be looked for simply in our desire to avoid litigation and other difficulties."

Dublin.—At the last meeting of the Dublin Town Council Mr. Healy gave notice that at the next meeting of the committee of the whole house on electric lighting he would move—"What progress had been made by the committee, the date when an order was given to apply for a licence, if that licence were obtained, and if not to explain the cause of delay, and as the committee had been sitting from time to time from the 2nd of May, 1887, if it would not be desirable to show more energy in the matter."—The Town Clerk said that a letter had been received from the Gas Company informing the Council of their intention to apply for a provisional order authorising them to supply electricity within the municipal boundaries of the City of Dublin. The Parliamentary agents, Messrs. Badham and Gore, had written suggesting that the representatives of the Corporation should attend in London last Tuesday to meet the representatives of the Gas Company in conference. Mr. Robinson moved "That the Lord Mayor, M.P.; Alderman Peter M'Donald, M.P.; and Messrs. Robert Sexton, Mayne, M.P., and Robinson, and the Town Clerk be requested to attend the conference." The resolution was adopted.

Barraclough and Co.'s Catalogue of Electric Wire Strand and Cable Machinery.—Of all the various trades and industries which have originated or have been largely extended by the great electrical developments of the last decade, it is safe to say that no industry has benefited more than the manufacture of insulated wires and cables. This prosperity has necessarily been shared to some extent by the makers of special machinery for stranding and covering insulated wire, and in order to keep pace with the times numerous improvements have from time to time been introduced in this class of machinery. Amongst those who have been actively engaged in this direction, the firm of Thomas Barraclough and Co. (of Manchester), whose latest catalogue lies before us, occupy a prominent place. The machines made by this firm are not, we believe, the cheapest in the market, but for excellence of design and careful workmanship, it is doubtful whether they are to be surpassed. The manufacture of insulated wires is a business in which the very best appliances are necessarily the cheapest in the long run. The catalogue before us describes machinery of well-nigh every description used in the trade, including the covering of single or stranded wires with cotton, silk, flax or jute yarns, braiding machines, horizontal taping machines, wire winding, stranding and cabling machines, sheathing machines, yarn tarring, and tanks for applying compound; also lead covering machines, hauling gear, &c., &c.

A Remarkable Lightning Discharge.—The following particulars of the effects of lightning are supplied to us by Mr. A. B. Tonkin, superintendent of the Direct Spanish Telegraph Company at Bilbao:—"During the afternoon of the 19th June lightning had been noticed several times, but the discharges were unimportant. At 5 o'clock the storm appeared to be gathering directly overhead; at the Ovienas Railway Station the Morse telegraph line and the telephone wires were put to earth. Immediately after this had been done there was a very vivid flash, which apparently entered by the Morse wire, exploded at the commutator with a loud noise, and, according to those present, taking the form of a sheet of flame, left the building by an open door. The discharge then crossed the siding for a distance of about 70 yards, and struck a young pine tree surrounded by a score of others. The pine was about 15ft. high, and apparently received the discharge at about seven feet from the ground, the trunk being completely severed, and, with the branches uninjured, the upper part of the tree was tossed a distance of several yards. The discharge then sought earth through the trunk, seven feet of which was broken in splinters, some of the latter over a foot long being thrown a distance of 60 yards, while others lay scattered about the foot of the tree. All that now remains of the tree is a piece of trunk, standing four feet out of the ground, split from top to bottom, the split being parallel with the railway station. The lightning on entering the ground opened a hole in the sand a foot deep all around the tree. A smaller pine standing a yard or two from the one destroyed is marked (bark stripped off) at four feet from ground, but otherwise uninjured."

The Proposed Central Station in Birmingham.—The *Birmingham Daily Post* of Monday last says:—"The preliminaries for bringing the electric light into general use in Birmingham are assuming more definite shape. The following official notice was served upon the Town Clerk on Saturday:—'To the Mayor, aldermen, and burgesses of the borough of Birmingham, acting by the Council, being the local authority for the borough of Birmingham within the meaning of Section 4 of the Electric Lighting Act, 1882, and to Edward Orford Smith, their town clerk.—On behalf of our clients, Messieurs Arthur Chamberlain and George Hookham, of New Bartholomew-street, Birmingham, electrical engineers, we beg leave to give you notice that it is the intention of the said Arthur Chamberlain and George Hookham, during this present year (1888) to apply to the Board of Trade for a provisional order authorising the said Arthur Chamberlain and George Hookham and their assigns to supply electricity for public and private purposes within the district of your authority. Dated this 30th day of June, 1888.—BARLOW, SMITH AND PINSENT.' Should the order be obtained, we understand that a month may elapse before the promoters will be required to specify the area for which the powers are required.

The Electric Lighting Act.—We have received a copy of the following letter, which has been addressed by Lord Thurlow to the "Executive Committee of the Electric Lighting Act Amendment Bill":—

"SIR: In thanking you for the valuable support and assistance you have extended to me as Chairman of the Electric Lighting Act Committee, without which support it would have been useless for me to have attempted to move in the matter, it affords me great pleasure to inform you that the Bill amending the Act of 1882, framed on the lines recommended by your Committee, and introduced by me into the House of Lords this year, has now passed both Houses of Parliament without material modification, and only awaits the Royal assent to become law.

"Under this Bill 42 years are substituted for 21 as the life of a provisional order, and 10 years for 7 for that of a license. More favourable conditions are also prescribed in the event of compulsory purchase by a local authority at the end of the term.

"I sincerely hope that this successful termination of our efforts during the last three years may render it possible to

Digitized by Google

attract the necessary capital to enable the electric lighting industry to advance without further delay on its career of utility, beauty and economy.

"My own opinion is that, with the alterations in the Act now effected, and with good management, no reason exists why electric light undertakings should not now prove commercially and financially successful, and become a well-recognised investment for capital, at least as profitable as gas shares or other equally popular securities.

"With reference to our Committee, I should propose that it be not dissolved, but continued in existence, so that it may from time to time be called together for deliberation and consultation as occasion may require. On this point I shall be glad to have the benefit of your opinion.—Yours, &c.,

"THURLOW.

"Anglo-American Brush Electric Light Corporation (Limited), 112, Belvedere-road, Lambeth, S.E., 26th June."

Messrs. Robey and Co.'s Exhibits at the Royal Agricultural Show.—At this show Messrs. Robey and Co. exhibited one of their well-known compound Robey engines, which are largely used in electrical installations and for driving machinery where steady running is required, for which work they are specially well adapted. This engine is very powerful for the space occupied, it works with perfect regularity with very varying loads, and is extremely economical in fuel, consuming under 2lb. of best Welsh coal per indicated horse-power per hour. The working parts are perfectly balanced so as to run safely at high speed, and having large wearing surfaces, it runs cool with heavy loads. It is well lubricated for long runs. The boilers of these engines are made to work with 150lb steam pressure; they are wholly of Siemens-Martins steel, and are carefully made by the most perfect machinery. Every rivet-hole is drilled in position by special tools, the horizontal seams are butt-jointed, and plated inside and out with double riveted strips. The mountings are all suitable for the high pressure at which the engine is worked, and every part of both engine and boiler is fitted and finished in the best style. Messrs. Robey and Co. also show a horizontal fixed engine fitted with Richardson's and Rowland's trip-gear. When steam engines are of large size and work with steam of high pressure, the working of the slide valves becomes an appreciable part of the load upon the engine, and to obviate this various kinds of equilibrium valve gear have been introduced, the best known among them being the Corliss with rotating valves, and the Sulzer, with Cornish double beat valves, a variety of which is also known as the Proell gear. All these gears are manufactured by Robey and Co., and can be fitted to their engines when required; but their own experience has led them to produce a "trip expansion" gear which is simple, effective, easily worked, and gives most satisfactory results. The cost of an engine fitted with this gear is necessarily greater than those with slide-valve gear, but the extra outlay is compensated for by the lessened wear and tear and greater efficiency; this is the more noticeable in the larger sizes. The trip gear can be fitted to all sizes, from 10 horse-power upwards, but is specially recommended above 30 horse-power nominal. The same firm exhibits a horizontal engine, medium stroke, which is made self-contained on one massive cast-iron foundation, with which are cast the main bearings. The crank shaft is bent out of a solid bar of steel and is especially strong, so as to resist heavy strains without risk of bending. It can take the fly-wheel on either side, as by this means the strain and wear are more equally distributed. When required, the fly-wheel can be on one side and a driving pulley on the other. This class of engine is specially useful where space is limited, or where the foundations are not good, as being self-contained they do not get out of truth with any settlement of foundations. It can be also placed upon an upper floor, and merely requires bolting to the joists. The engine is governed by automatic expansion gear controlled by Richardson's patent automatic governor, so that economy in steam and regularity in running is maintained with very varying loads. The cylinders are fitted with a liner of specially hard metal surrounded by steam jacket, suitable adjustment and efficient lubrication supplied to all working parts, and the whole engine is of the highest workmanship and material. We have lastly to mention a vertical engine of new design, erected on a massive cast-iron standard, which also forms the bed-plate, carrying a bent crankshaft, and admitting of a fly-wheel or pulley on either side. The engine is fitted with Richardson's patent spring governor, which is most powerful and sensitive in its action, and which, acting direct through a slot link and die, automatically controls the steam admission to the amount required for the work being done. All wearing surfaces are large, and fitted up with the most perfect accuracy and fit by special machinery for the purpose. Every part is made to template, and only the best materials and workmanship are used throughout.

Earth Current and Magnetic Observations at Greenwich. The annual report of the Astronomer-Royal, which has been issued, contains the following:—"The earth-current wires, which were damaged by the snowstorm of December 26, 1886, were not completely repaired till August, 1887, when it was found that the earth-plate at Angerstein Wharf had been stolen, another earth-plate being then supplied. A renewal of the earth-current wires concurrently with the telegraph wires on this portion of the South-Eastern Railway was arranged, in concert with Mr. Leonard, but this has not been carried out, owing to a rise in the price of copper. Five measures of resistance of the earth-current wires have been made since the last report, but the results are not satisfactory, owing presumably to the bad condition of the wires. On the line from Angerstein Wharf to Ladywell, 7½ miles in length, the measures of resistance range from 220 to 285 ohms, and on the Blackheath to North Kent East Junction line, five miles long, the measures range from 230 to 262 ohms. Under these circumstances it seems hopeless to attempt to express the measures of ordinates on the earth-current sheets in terms of the electrical units until the conditions of the circuits have been improved. A further difficulty arises in discussing the small diurnal inequality on the earth-current registers in consequence of the circumstance (to which attention was first drawn by Mr. A. J. S. Adams, of the Post Office Telegraphs) that there is a slight dislocation in the Angerstein Wharf to Ladywell trace shortly after sunset with sudden return to the original position shortly before sunrise, representing an increased current from Ladywell to Angerstein Wharf, or a diminished potential at Angerstein Wharf during the night hours. Possibly this may be connected with the electric lighting in the vicinity of the earth plate. It appears to have commenced in 1883, becoming more pronounced in 1884. The following are the principal results for the magnetic elements for 1887:—

Approximate mean declination	17° 47 W.
Mean horizontal force	3·9419 (in British units) 1·8175 (in metric units)
Mean dip	67° 25′ 45″ (by 9in. needles) 67 26 20 (by 6in. needles) 67 27 13 (by 3in. needles)

In the year 1887 there were only three days of great magnetic disturbance, but there were also about twenty other days of lesser disturbance for which tracings of the photographic curves will be published, as well as tracings of the registers on four typical quiet days."

UNIPOLAR INDUCTION.—V.

BY G. W. DE TUNZELMANN, B.SC.

(Continued from page 234.)

The subject of so-called unipolar induction has for some time past attracted the attention of a considerable number of physicists, and it will, I think, be of interest to consider their methods of treating it, and more particularly the theory advanced by Edlund for the explanation of the phenomena, as it has excited a good deal of interest, and his more important Papers have been translated and published in the *Philosophical Magazine*. The method, originally due to Faraday, of seeking for the explanation of electrical phenomena in the action of the media surrounding the conductors, in spite of the splendid manner in which it has been developed mathematically by Sir William Thomson and Clerk Maxwell, has as yet been adopted by very few of the Continental physicists, who, as a rule, still remain content with investigating electrical phenomena by mathematical methods which only take account of the actions in the conductors, and entirely ignore those in the surrounding media, a course which often places them at a considerable disadvantage. Thus, in the case we are now considering, the rotation of a cylindrical magnet about its axis, the field, as far as it can be expressed as a function simply of the distance from the axis, is unaltered by the rotation, and therefore a discussion as to whether the lines of force remain fixed, or rotate with the magnet is entirely without meaning, as long as we confine our attention to the distance actions between the magnet and the conducting circuit, and take no account of what takes place in the intervening medium.

In 1877 E. Riecke (Wiedemann's *Annalen*, Vol. I.) published an investigation of the phenomenon of unipolar induction, founded on the consideration of the E.M.F. produced by a magnetic pole in a conductor moving relatively to it, and, as he started with the assumption that the E.M.F. was a function only of the relative linear velocities and of the distance of the pole from an element of the circuit, he naturally arrived at the conclusion that the rotation of a magnet about its axis would produce no effect in any case, except that due to the translatory motion of its peripheral relatively to its central portions, and therefore at the same result as Faraday and Plücker, that a statical electrification would be produced on the surface of the magnet.

In the same year Edlund (Wiedemann's *Annalen*, Vol II.) published a paper on the relation between electro-magnetic rotation and unipolar induction. When a battery is included in the circuit of the wire *a c b* (Fig. 12 of Article III.), the current is sent through the jacket, and the latter is made to rotate. Edlund points out that it follows from the mechanical theory of heat that the heat produced by the current through the jacket will be less, by an amount equivalent to the work required to produce the rotation, than if the jacket were kept at rest, and that this would involve the production of a current by the rotation in a direction opposite to that of the current producing it, and it follows immediately that the strength of the current due to the rotation must be proportional to the product of the magnetic moment of the magnet into the angular velocity of rotation, divided by the resistance of the whole circuit, or the E.M.F. produced must be proportional to this product and independent of the resistance. In the same Paper he propounds his theory which is more fully developed in his "Researches on Unipolar Induction, Atmospheric Electricity, and the Aurora Borealis," published in the *Kongl. Svenska Vetenkaps-Akademiens Handlingar*, Vol. XVI., and translated in the *Philosophical Magazine*, fifth series, Vol. VI., 1878. In these Papers he points out that when a current is passed through the wire and jacket the magnet remains at rest, and the magnet can therefore be turned about its axis without any resistance due to action between the current and the magnet. It therefore follows that no current would be produced in the circuit by the rotation of the magnet, a result which we have already seen to be true, and which has been explained on the assumption that the magnetic field rotates with the magnet. He then proceeds to point out that when the magnet and cylinder are rigidly connected the magnet is carried round with the cylinder. He then infers that the action of the magnet on the rotating cylinder is the same when it revolves with it as when it remains at rest, so that a magnet can, he asserts, produce unipolar induction in a conductor with which it is fixedly united. Edlund here, like Faraday and Plücker, overlooks the fact that there is another possible explanation, namely, that when the magnet and cylinder rotate together the induction arises, not in the cylinder, but in the fixed portion of the circuit.

He then recalls the known fact that a metal ring surrounding a magnet and traversed by an electric current, will if movable, transport itself along the magnet. If the current in the ring is in the same direction as the molecular currents in the magnet, it will remain in stable equilibrium at the equatorial portion of the magnet, but if the current in the ring is in the contrary direction to the molecular currents, it will be in stable equilibrium at the centre of the magnet, and if displaced in either direction it will move towards the nearest pole and continue moving away from the centre until it passes beyond the poles of the magnet.

Now if the electric current be assumed to consist be the translatory motion of a fluid in the positive direction, or of two fluids in opposite directions, then, when the cylinder is made to rotate the fluid or fluids will rotate in the same direction, and form currents circulating horizontally round the magnet, and of intensities proportional to the velocity of the rotation. If there are two fluids these currents will differ from ordinary currents in that both fluids will move in the same direction, while in ordinary electric currents they move in opposite directions. If there is only one fluid there will be no distinction between the currents due to rotation and ordinary electric currents. Now, according to the usually received ideas, the action of the magnet upon the negative current would be the same as its action on a positive current in the opposite direction. The action of the poles of the magnet upon these currents will therefore, from the experiment with the rings previously described, cause the cylinder to receive an excess of positive fluid at the extremities and an excess of negative fluid at the centre, or, according to the author's view, an excess of ether at the extremeties and a deficiency at the centre, or *vice versa*, according to the direction of the rotation and the position of the poles. It will follow from this theory that a current will be produced in a wire having one extremity in contact with the part of the cylinder adjacent to a pole of the magnet, and the other in contact with the part adjacent to the centre.

Edlund then shows that the E.M.F. produced in the cylinder will on this theory be proportional to the product of the strength of the magnetic pole into the angular velocity of the cylinder as required by the mechanical theory of heat.

He then proceeds to apply his theory to the experiment illustrated in Fig. 11, Art. II., the plate being rotated, while the magnet remains fixed, and shows that it leads to the conclusion that there exists a certain circle on the disc *a*, concentric with the disc, which he calls the neuter circle, such that for a given direction of rotation the electric molecules situated outside it will be directed by the magnetic force towards the periphery of the disc, while those which lie inside it will be directed towards the centre, the radius of the circle depending on the length of the magnet, and the distance of the disc from the nearest pole. If the points of contact *c* and *d* are outside this circle the current will flow from the centre of the disc to the periphery, while if they are within the neuter circle the current will be in the opposite direction, and if the points *c* and *d* are on opposites sides of this circle they can be selected so that no current will be produced. These phenomena have been obtained experimentally by Felici (*Annales de Chimie et de Physique*, third series, Vol. XLIV.). They follow at once, quite independently of Edlund's theory, from the consideration of the lines of force of the magnet, for near the centre of the disc the largest number of lines of force from the nearest pole will pass through the disc in the direction away from the pole, while near the periphery of the disc, if it is large enough, more lines will pass in the opposite direction, these being the former lines coming round towards the more distant pole of the magnet. There

Digitized by Google

must therefore be a circle concentric with the axis of the disc, such that an equal number of lines pass through the area enclosed by it in opposite directions, and this will be the neuter circle of Prof. Edlund, and will clearly account for the phenomena observed by Felici. Edlund applies his theory to several other of the experiments already described, and also describes two new ones which he considers, in addition to the existence of the neuter circle described, tend specially to confirm his theory.

The first of these was made with the apparatus shown in Fig. 18. *a b c d* is a rectangular framework, composed of two brass bars, *a b* and *c d*, joined at the ends by brass cylinders, *a c* and *b d*. These cylinders are movable, and can be fixed at any desired distance from the line joining the centres of the bars *a b* and *c d*, and either on opposite sides or on the same side of it.

The centre of the bar *c d* is in contact with the magnet, and to the centre of the bar *a b* a cylinder *o* is soldered surrounding the centre of the magnet. This cylinder is connected by means of a contact spring, *t*, with the galvanometer wire *l*. The other galvanometer wire *l'* is connected with a mercury cup attached to the magnet at *s*. Edlund then made a series of observations of the strength of the current in the galvanometer circuit when the apparatus was made to rotate, and he found that the current produced at a given speed of rotation was independent of the position of the brass cylinders *a c* and *b d*, and also remained uncharged when one of them was removed, as was required by his theory, bearing in mind that the resistance of the circuit would not be sensibly altered by removing or altering the position of either one of the cylinders, since the resistance of the brass work would be an infinitesimal fraction of the total resistance of the galvanometer circuit.

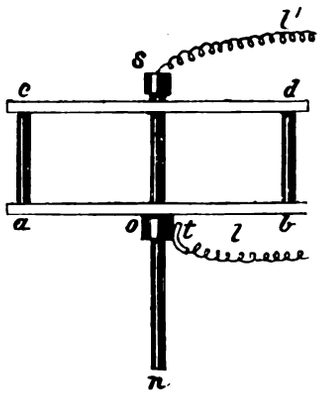

FIG. 18.

n s, cylindrical magnet; *c d*, brass bar in contact with magnet; *a b*, brass bar insulated from magnet; *o*, cylinder soldered to bar *a b* and surrounding equatorial portion of magnet; *l l'*, galvanometer wires connected with rubbing contact spring *t* and mercury cup at *s*; *a c* and *b d*, movable brass cylinders.

He does not state definitely in the Paper whether the magnet was rigidly attached to the brass rectangle, and revolved with it; but I should infer from his description that it was so. On his theory the rotation of the magnet would have no effect on the induction produced in the brass rectangle.

The results of these experiments follow at once from the theory which I have endeavoured to show must be the true one, that the lines of force revolve with the magnet, for the area of the circuit increases continually during the rotation, and the increase at each revolution of the number of lines of force passing through it is equal to the total number of lines proceeding from the magnet which cut both the moving and the fixed portions of the circuit. The same current will also be produced if the magnet remains fixed; but in this case the induction will take place in the brass rectangle, while in the former case it was due to induction in the fixed galvanometer circuit.

(To be continued.)

The Cruto Lamp.—A Cruto lamp factory has recently been started in Paris by the Société de Soudure Electrique des Métaux, and 200 lamps a day can at present be turned out.

THE GAULARD AND GIBBS PATENT ON SECONDARY GENERATORS.

The following is the full text of the amended specification of Messrs. Gaulard and Gibbs, which is the subject of the action which is now before the Court of Chancery. The words which stood in the original specification, but which have since been deleted by permission of the Controller of Patents, are printed in smaller type. Words which have been inserted or substituted in the same way are printed in italics:—

SPECIFICATION in pursuance of the conditions of the Letters Patent filed by the said Lucian Gaulard and John Dixon Gibbs in the Great Seal Patent Office on the 13th March 1883.

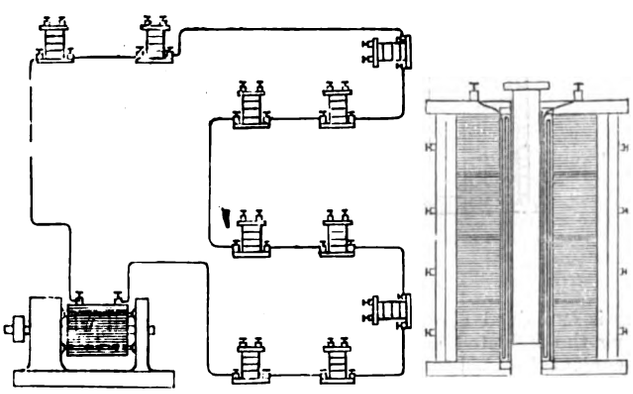
Lucian Gaulard of Montague Place Bedford Square and John Dixon Gibbs of Bury Street St James both in the County of Middlesex A new system of distributing electricity for the production of light and power"

This system consists of the employment of an alternating current produced by an electro dynamo machine and determining by its passage through an unlimited *a* number of electrical generators of special construction the formation of induced currents of which the quality and the value depend only on the construction of the secondary coils of the said electrical generators.

The currents generated under these conditions are utilised either by lamps to produce light or by magneto machines to produce motive power.

The principle which is the basis to this system of distribution is the following.

When an electric current approaches to or recedes from a closed circuit of solenoidical form it determines in this latter an induced current without the value of the primary current being in any way modified; experience shows that the alternation of a primary current gives rise to an induced current under the same conditions as the passage and interruption of the said current.



FIGS. 1 AND 2.

In further explanation we would compare the phenomenon just mentioned to that produced by the working of magneto-electric machines. In effect in these latter the induced current is produced, the value of the magnetic field remaining constant by the approaching of the bobbins to and their receding from the magnetic poles and experience shows that the value of the current produced is in exact proportion to the speed of passage or rotation.

In the machine of Pixii which was the first constructed the current was generated by the rapidity with which the poles were alternatively brought before the bobbin.

In utilising alternating currents the phenomenon produced in our induction machines may be compared to that produced by the machines of Pixii.

This explained it is easy to understand the working of our system.

We take an alternating current dynamo machine constructed in such a manner that the resistance of the inducted system ("induit") is greater than that of the external circuit uniting its two extremities, *but we do not use or desire to use alternating dynamo machines that produce currents other than currents of high tension as hereinafter firstly claimed.*

Let us suppose the length of this circuit equal to 50 kilometres we place (see Figure 1) upon it at every 500 metres for instance a secondary generator constructed in the following manner.

The secondary generator may be constructed as represented in Figure 2.

Upon a central exciting core of soft iron wire is rolled a copper wire of about 3 millimetres diameter and perfectly insulated in 3 rows of superposed spires. On the cylinder thus formed are placed bobbins on which a cable is wound composed of 6 copper wires of half a millimetre in diameter each strand being insulated by means of paraffined cotton. The ends of the cable of each bobbin are so placed as to allow of their being grouped for quantity or tension.

These bobbins constitute the secondary coil to the poles of which are fixed the apparatus of consumption. The first wire, on the other hand, through which the initial current circulates constitutes the primary coil.

Digitized by Google

A more powerful generator may be formed by means of several columns of bobbins arranged in that case vertically in parallel rows.

The secondary coils of these columns are connected with one another by a central commutator.

Or preferably the following construction is adopted.

A cable (see Fig. 3) is composed of a central copper wire of 4 millimetres diameter perfectly insulated around which are placed parallel to its axis and completely surrounding it 6 cables each composed of 12 copper wires of half a millimetre diameter individually insulated with paraffined cotton or other insulating material.

This cable is rolled on a hollow cylinder made of wood, for example 50 centimetres long and 6 centimetres in diameter and each layer of spirals is separated from the other by 2 cylindrical segments of iron 2 millimetres thick and without contact in order to avoid the creation of heating Foucault currents.

The extremities of the six fine wire cables are united to a commutator which allows of their being grouped either in tension or quantity.

The object of this disposition is to utilise the radiating inductive action of the inductor formed by the wire of 4 millimetres placed in the centre of the cable and to prevent the reaction of the spirals composing the inductor on one another.

The columns formed as above described may be placed vertically on a platform in the number proportionate to the power it is desired to give to the machine thus constructed and the extremities of their inductors are connected with a commutator so as to allow the passage of the primary current through one or more of the columns.

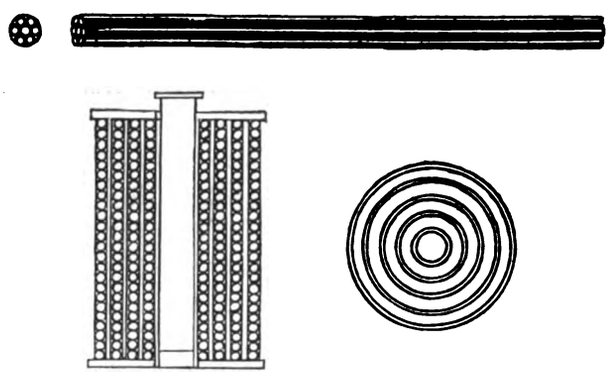


FIG. 3.

As is explained above the extremities of the small wires composing the inducted system ("induit") and on which is gathered the current destined to be employed are grouped in tension or in quantity so as to vary the tension according to the requirements of the consumer. Lastly, in the centre of the columns, exciting cores enable the graduation of the potential of the current generated on the induced system ("induit").

Now the primary current in passing through this primary coil is subject to no other modification than that caused by the resistance of this said primary coil hence the currents generated by the hundred secondary generators placed upon the circuit will have changed the value of the primary current only in proportion to the sum of the resistances of their primary coils which resistance will be compensated in the construction of the inducted system ("induit") of the primary generator.

Under these conditions it is easy to understand that the number of secondary generators may be indefinitely multiplied upon the circuit, and that according to the theory explained above the value of the currents generated (the initial alternating current remaining constant) will depend only on the construction of the secondary coils of the secondary generators.

From which it results that secondary generators of similar construction will give absolutely identical currents capable of being advantageously employed in telegraphic systems and thus the problem of the suppression of batteries for telegraphy is solved.

To sum up We claim in accordance with the law.

First. The privilege of exclusively working our process of distribution characterised by the following points as above explained. The employment of an alternating current of high tension for the generation on an unlimited a number of secondary generators of induced currents individually utilised either for the production of light or motive power.

Second the system of electric distribution such as is laid down in the foregoing statement.

Third. The special construction as described of secondary generators designed to produce this result

In witness whereof we the said Lucian Gaulard and John Dixon Gibbs have hereunto set our hands and seals this twelfth day of March in the year of our Lord One thousand eight hundred and eighty-three.

L. GAULARD (L.S.)

J. DIXON GIBBS (L.S.)

EDISON AND SWAN ELECTRIC LIGHT COMPANY v. HOLLAND AND OTHERS.

It will be remembered that at the last hearing on the 31st of May, an adjournment was agreed to in order that certain experiments might be carried out. Prof. Stokes, P.R.S., was afterwards requested to witness these experiments, and to make an independent report to the learned judge. The report has not been read in court, but the full text will be found at the end of the present report.

This case was resumed before Mr. Justice Kay, at the Royal Courts of Justice, Chancery Division, on Monday last.

The plaintiffs' counsel were as follows:—The Attorney-General (Sir R. Webster), Mr. Aston, Q.C., Mr. Moulton, Q.C., and Mr. Bremner; and the defendants', Sir Horace Davey, Mr. Finlay, Q.C., and Mr. Graham.

Before Mr. Finlay commnced his speech for the defendants,

Mr. JUSTICE KAY said that he had received two letters from Prof. Stokes, who had been appointed to report on the experiments made in the presence of both parties, in which he set out a memorandum from the defendants' counsel that no experiments should be made by witnesses connected with the case. His lordship asked Mr. Finlay if the defendants still insisted upon that objection. He was surprised, and he should not have listened to such an objection for a moment.

Mr. FINLAY replied that he did not insist upon the objection.

Mr. JUSTICE KAY went on to say that Prof. Stokes was prepared to put himself in the witness-box to give any explanation that was desired, but he did not think that it was necessary to call the Professor. He might remind learned counsel that this case had been on for twenty days, and it had been well argued out in the witness-box, and therefore it was unnecessary to go into elaborate arguments, and he hoped they would keep their speeches within reasonable limits.

Mr. FINLAY then commenced his speech for the defendants. He proposed to make observations, first upon the Edison patent, and secondly on the Cheesborough patent. First, with regard to the Edison patent, attention was directed to the fact that a judgment had been given in the Court of Appeal upon this patent; but before calling attention to the form of that judgment, he might say that the evidence now had put the facts of the case in a very different light from that in which they stood at the time that judgment was pronounced. In the first place the Court of Appeal decided the former case under the belief that this patent of Mr. Edison's had been the cause of a great outburst of incandescent lighting, and that there was some advantage in the high-resistance lamp *per se*, taking it as an individual lamp and not merely for the purposes of an arc light. Consequently the Court of Appeal believed on the case as presented to them, that the lamp F J B 1 was the only lamp of any importance which Mr. Swan had prepared; that F J B 1 was a mere experiment, and an abandoned and an unsuccessful experiment; and the Court were not in possession of the facts as to what Mr. Swan had done with reference to incandescent lighting. The Court of Appeal, as well as Mr. Justice Butt, who was the judge in the first instance, were led to believe that the lamp F J B 1 (Mr. Swan's lamp) was formed after carbonisation, that the carbon had been rubbed down into the shape which it presented in the lamp. From the judgment of the Court of Appeal it appeared that the sufficiency and utility of the process described in the Edison patent were practically admitted by the Woodhouse and Rawson case on all these points, but he submitted that the present case stood in a different position from the Woodhouse and Rawson case. In the first place, with regard to the impression which the Court entertained there that this patent had been the cause of a great outburst of incandescent lighting, and that there was some advantage in high resistance for the purpose of a lamp taken by itself, he very shortly desired to call their lordships' attention to the facts as they now presented themselves. It was now undisputed that no Edison lamp was ever seen until long after the date of the patent now in question. It had been proved by witness after witness that the first Edison lamp that they saw in Europe was in September, 1881, at the Paris Exhibition, and the first time that they saw an Edison lamp in this country was at the Crystal Palace Exhibition in the autumn of 1882. Sir F. Bramwell, who was the first witness called for the plaintiffs, said that the only lamp which in the present instance was cited as a specimen made under this patent was made of parchmentised thread; and he very frankly said that the thread had been subjected to the process known as parchmentisation. At every stage of the course of manufacture secret processes were used by the plaintiffs. That was confirmed by Dr. Fleming and Dr. Hopkinson. So far from it being the case that this patent was the cause of the outburst of incandescent lighting, there was no evidence whatever that a single lamp made according to this specification had ever been sold; and it was now undisputed that no thread lamps unparchmentised had ever been manufactured by the plaintiffs, except for the purpose of litigation. No tar putty lamps had been sold, and the six Edison lamps which were referred to by Dr. Fleming as having been given to him by Mr. Johnson in 1880, contained horse-shoe paper filaments, and these were made by a subsequent patent to that which his lordship's attention was directed. The two lamps given to Dr. Hopkinson, also by Mr. Johnson, in March, 1880, were made in the same way. He thought there was no evidence of anything further being done with the Edison lamps after these six lamps given by Mr. Johnson to Dr. Fleming early in 1880, and the two

Digitized by Google

given in March, 1880, to Dr. Hopkinson, until the Paris Exhibition in September, 1880. If the plaintiffs' view, which prevailed in the Court of Appeal in the former case, were correct, that Edison's specification in this patent solved this difficulty, which had hitherto impeded the march of electric lighting, it was a most extraordinary fact that in the course of this case, which had lasted over he was ashamed to say how many months, and in which no expense had been spared, the plaintiffs had given no evidence whatever of lamps made either here or in America just after this so-called solution of the problem; and the Edison Electric Light Company was registered in March, 1882. One exhibit was produced in the course of the case by Dr. Franklin, marked E F 1. It was given to him by Mr. Edison's agent in 1882, and Prof. Thompson told his lordship that the Edison lamps at the Paris Exhibition were like E F 1. That lamp, E F 1, differed from Edison's specification in ten different respects, to which Prof. Thompson called attention. Prof. Thompson called attention to subsequent patents that Mr. Edison himself had utilised in the manufacture of those lamps. That circumstance by itself, coupled with the absence of all evidence of manufacture of lamps under this specification, would be sufficient to dispose of the claims of the former case, that this patent was a cause of the outburst of incandescent lighting, and must, therefore, have been of some great benefit. But they had further evidence in the present case. There was no better judge than Mr. Swan if the difficulty had been solved, for Mr. Swan had been studying the subject for some considerable time. Mr. Swan said that the specification of this patent made very little impression upon him, and the only novelties to him when he read it were with regard to matters of detail; and then he specified what those matters of detail were, namely, the tar putty, the method of mounting, the use of very thin platinum wires, the use of camphor and oxide of zinc, and the use of the word "filament." Mr. Swan said that he did not suggest in November, 1879, that there was any novelty in an incandescent lamp consisting of a glass bulb, exhausted, with a carbon conductor and leading-in wire, and he said there was no novelty in making the carbon of any particular size. He (the learned counsel) submitted that this circumstance in the evidence of the present case effectually disposed of the claim which was set up in the previous case, in which the Court of Appeal gave judgment to the effect that this patent marked an epoch in the history of electric lighting. The true history of electric lighting was before his lordship, as it was not before their lordships in the previous case. That claim was entirely unfounded when all the evidence was examined.

In the second place, the Court of Appeal decided that case under the impression that F J B 1 was the only lamp of Mr. Swan, that there was a failure, and that Mr. Swan abandoned it as an unsuccessful experiment. He wished to call attention to the salient features of the present case, which would put a new light upon it altogether. His lordship had the evidence of Mr. Proctor, Mr. Heaviside, Mr. Mayfield, Mr. Patterson, Mr. Mess, Mr. Blackburn, and Mr. Swan, and his coadjutor, Mr. Stearn, which showed very plainly the continuous work done by Mr. Swan in co-operation with Mr. Stearn; and the admission made by these two last named gentlemen showed that the assumption to which he had referred had proved to be entirely erroneous. Mr. Swan admitted that towards the end of 1879 he made his hairpin-shaped Carré carbon lamps, and he said that he had ordered those lamps from Messrs. Carré in the spring of 1879. J W S 1 was produced as an exact model of this carbon, and the diameter was $\frac{1}{32}$th of an inch. Some difficulty was experienced in mounting these Carré carbons, but the fact that these carbons were used in the summer of 1879, at a date considerably anterior to November, 1879, when the provisional specification was taken for Edison's patent, was put beyond doubt by Mr. Swan's own admissions. Mr. Swan said that he made a parchmentised-thread lamp in the middle of 1880, and he made a considerable number of them in the autumn of 1880. Mr. Thompson said that Mr. Stearn's house was lighted with those lamps in the autumn of 1880. It was not suggested now that Mr. Swan and Mr. Stearn in what they were doing at the date of this patent owed anything to the patent of 1879. In 1880 they made lamps of parchmentised thread; but until he heard the reply on the part of the plaintiffs he would not believe that they were indebted to Mr. Edison for the patent now in question. The date of the various exhibitions of lamps was proved by several witnesses. The exhibition of Swan lamps at the Institute of Civil Engineers took place on the 30th November, 1880. Mr. Spottiswoode's house was lit up with Swan's lamps in December, 1880. Prof. Perry tested a number of Swan lamps in May, 1881. Swan lamps were exhibited at King's College in July, 1881, and at the British Association in August, 1881. They were exhibited further at the Paris Exhibition next month, in Sept., 1881, and that Exhibition in Paris was the first occasion on which the Edison lamps were seen, according to his clients' witnesses, apart from the specimen which was given by Mr. Johnson at the date that he had already mentioned. In 1881 there were 1,000 Swan lamps running at the Savoy Theatre, and the first Edison lamps seen in this country was at the Crystal Palace Exhibition in 1882. E F 1 was presented by Mr. Edison's agent to Dr. Frankland, who spoke, along with other witnesses, to the fact that that E F 1 exhibited was not made according to the patent now under consideration; and that was put beyond doubt by the evidence of Prof. Thompson. With regard to the Swan lamps which were exhibited in Paris in September, 1881, Prof. Thompson pointed out that they were like F J B 1. In material respects they differed in having smaller carbons and in the leading wires coming out at the same end of the globe. To the straight conductor as used (F J B 1) Prof. Thompson explained there was no objection at all, and that was shown by the fact that the plaintiffs themselves made such lamps. The learned counsel then called attention to two patents that Mr. Swan took out in 1880. On the 2nd January, 1880, he took out the patent, No. 18, for running on the pumps, as it had been called, on the importance of which he need not say a word. On the 20th January, 1880, he took out a patent for two purposes: No. 250 for preventing cracking and leakage of the gas bulbs by heating of the leading wires, and for parchmentising paper. On the 27th November, 1880, he took out a patent for parchmentising thread (4,932), and on the 2nd December, 1880, he took out another patent (5,014), which differed from the patent of the 27th February, 1880, in containing directions for packing the thread to be carbonised with charcoal powder. He submitted that, taking the evidence in this case, to the salient points in which in this connection he had endeavoured to direct his lordship's attention, it was now plain that, so far from Edison's patent marking an epoch in the history of incandescent lighting, it was merely one stage in the process—by no means an important one—which contained nothing new in principle, and which did not reveal any process which had been used for practical purposes. Mr. Swan and Mr. Stearn were working at the subject, and they were working with results which led to the formation of Mr. Swan's company, and to the subsequent amalgamation with Mr. Edison.

In the third place, Mr. Justice Butt and the Court of Appeal in the last case were led to the conclusion that the lamp F J B 1, which Mr. Swan produced, had been formed by rubbing or cutting the carbon after it had taken the form of carbon in the shape it assumed in the lamp. In the opening speech of the Attorney-General before Mr. Justice Butt this impression was conveyed. The Attorney-General said:—"I ask your lordship to let me pause for a moment to say that the main discovery of Mr. Edison in this connection was the utilisation of filament or thread of carbon, meaning thereby a substance which is made into a filament or thread, or may be made into a filament or thread before it is carbonised. I shall show that attempts to light by cutting down blocks of carbon, by sweating them down from a thick piece to a thin piece, had been thought of and had failed, and even now failed with all the knowledge that we have at the present time. But the point, the touchstone of the invention which he discovered, which has made the thing from being a mere laboratory experiment into practically useful article, was the use of a filament or thread; that is to say, something which is made of thread or made of filament before it is carbonised." Sir Richard Webster further said this, "In addition to that, there is the most important thing which I ought perhaps to have put first, the capability of shaping your bridge before you carbonise—that is to say, you can twist into the spiral shape or any other shape, as Mr. Edison says, and that you can do before it is carbonised. In other words, it will turn out that the idea of making a lamp first, or making the shape of the conductor and then carbonising, was the root of the discovery which led to the success of Mr. Edison's lamp." In support of that, evidence was given on the former trial by Sir Frederick Bramwell and Dr. Hopkinson, and Mr. Swan was in court whilst that case was going on, and Mr. Swan knew the facts; and because it was suggested that he had been subpœnaed by the other side he felt himself cut off from his friend, and allowed the Court to decide the case with the idea that the lamp F J B 1 had been so formed. The facts were now before his lordship, and it was unnecessary that he should comment upon them.

In the fourth place, the Court of Appeal had decided in the former case that the sufficiency and utility of the processes decided in this patent of Mr. Edison's were practically not disputed. Now, he desired to say a few words on the construction of this patent by Mr. Edison, and he would then, so far as his lordship thought it desirable, call attention to the judgment of the Court of Appeal in the former case. The first claim was for

> "An electric lamp for giving light by incandescence, consisting of a filament of carbon of high resistance made as described and secured to metallic wires as set forth."

The true construction of that was that the lamp was there used to denote the light-giving portion of the lamp. The word lamp, he submitted, was not used as a general term to describe the whole apparatus, including the bulb, but used to denote what gave the light in the lamp, and this was strongly corroborated by the light thrown upon the use of that word lamp in the provisional specification, where his lordship would see that the word lamp was clearly used to exclude the bulb. The second claim was the

> "Combination of a carbon filament within a receiver made entirely of glass, through which leading wires pass, and from which receiver the air is exhausted for the purpose set forth."

He submitted that according to the ordinary rules of construction that must be read in this way as meaning the combination of a carbon filament, made as described, with a receiver made entirely of glass, through which the leading wires passed, and so forth; that it would be enlarging the scope of the claim unduly to consider it as doing anything more than this—to say, "I have described in my first claim that I claim the manufacture of the light-giving portion of the apparatus, which I there call lamp, in a particular way. In my second claim I refer to the fact that I combine that light-giving portion of the lamp with a receiver made entirely of glass, through which the leading wires pass, and from which receiver the air is exhausted for the purpose set forth, and that combination I claim." He submitted that that second claim should not be read as a claim for a carbon filament, except such a carbon filament as was referred to in the first claim "made as described." There were two other claims which he need not particularly describe, but he proposed to call attention to the judgment of the Court of Appeal as to how far that judgment was binding upon his lordship in the present case.

The learned counsel, having cited the judgment, went on to say it was known that there were advantages in previous patents, that high resistance could be got by diminishing the sectional area as well as by increasing the length of the conductor. The previous patents had been taken, and the wires had been used for conductors for small sectional area, for this very purpose. Could it be said that if an inventor came forward and said, "Oh, I diminish the sectional area of the carbon conductor,"

Digitized by Google

that that principle was a good matter for a patent? He submitted that there was no novelty or subject matter of a patent in such a claim.

Mr. JUSTICE KAY: You say that Edison was the first person who had made a commercial success of the lamp?

Mr. FINLAY: Yes; and Dr. Hopkinson puts it "that Mr. Edison's merit was in using a smaller cross section, and in the way in which he shows you how to make it." With regard to the point, of which so much was made in the previous case, the forming filament paper carbon, he need only remind his lordship that all the Carré conductors were first formed and then carbonised. That was one of the admissions of the case, and Mr. Swan knew that perfectly well. What were the limits of Mr. Edison's patent? Was it a patent for carbon conductors of high resistance? He submitted that when a man took out a patent he ought to set up boundary marks to enable the public to know when they were trespassing, and which was forbidden ground. There were really no limits here. Mr. Edison did not say I claim the carbon conductors of less than a certain sectional area, but the claim now put forward was a vague claim to all carbon conductors of high resistance. The absence of any definition as to when you became a trespasser was sufficient to vitiate such a claim. With regard to the use of the lamps manufactured by Mr. Swan, he said that he did not make a thread lamp before the middle of 1880, and that they were always parchmentised. He also said that during 1879 he was not making any horseshoe carbon lamps. Mr. Swan must be mistaken in that, and he said that for dates he depended entirely upon the correspondence. Mr. Stearn said that he made no thread lamps before January, 1880.

Mr. JUSTICE KAY: Were these experiments between Swan and Stearn?

Mr. FINLAY: Mere experiment I should not rely upon. But there was no secrecy in the matter; publicity was given to it by being shown to various persons.

Mr. JUSTICE KAY: Do you mean to say that Mr. Swan could not have taken patents out afterwards.

Mr. FINLAY: That, of course, my lord, is the test. It is very important from another point of view—the continuity of Mr. Swan's work.

Mr. JUSTICE KAY: All these gentlemen were running a race.

Mr. FINLAY: I will not go through Mr. Stearn's evidence, but I shall just refer to the names of the witnesses who were called as to the lamps of Mr. Swan and Mr. Stearn—Mr. Proctor, Mr. Heaviside, Mr. Patterson, Mr. Mayfield, Mr. Ridley, Mr. Meas, Mr. Blackburn, Mr. Turner, and Mr. Allen.

Mr. JUSTICE KAY: They were assisting; that would not be enough.

Mr. FINLAY: I agree with that. I will call your lordship's attention to Sir Frederick Bramwell in answer to Mr. Lane-Fox.

Mr. JUSTICE KAY: Sir Frederick Bramwell says Mr. Lane-Fox knew a great deal more about it than Mr. Edison had any idea of.

Mr. FINLAY: Yes; and he also says this: "That the only point which he suggests between the provisional specification of Mr. Lane-Fox and Mr. Edison's patent is that which he calls his luminous bridge, proposed to make of a compound material, namely, carbon of some non-conducting material finely ground and mixed together; but there is no suggestion of carbonising after the material is so mixed and the bridge is formed to shape. There is as regards mixture and mode of material an important distinction. He submitted that this specification of the previous patent, really apart altogether from the lamps of Swan and Stearn, prevented there being any novelty in respect of which the claim had been made.

The learned counsel then passed to another head of the case, namely, the insufficiency of the description of the processes. That might be put either as insufficiency or non-utility. They were not charged with the infringement of a process. But he submitted that even if the second claim be read, if the processes given or any of them were insufficient, that the patent was bad. This case had been going on from July, 1886, and they had deliberately abstained from giving the Court the advantage of Mr. Edison's evidence. If Mr. Edison, in a case of such importance, could not find the time necessary to protect the interests of his own company, why had they not taken his evidence in America? He submitted there was one explanation, namely, that Mr. Edison found the process as indicated in the patent of November, 1879, in practice, really useless, and the first time that he got hold of the process to work in practice was when he embodied it in the patent of March, 1880, where it was described as in the horseshoe form. Why Mr. Edison was not called he left it to his lordship to decide.

Now, the first observation he made was one which did not require dwelling upon, and that was the undoubted fact that no lamps had been made under the patent of 1879 except for the purpose of litigation. And, secondly, that no man who would answer the description of the skilled working man had produced lamps under this process; they had been made by experts, who were in a different position for dealing with processes of this kind from the skilled working man, who was calculated to be sufficiently instructed by this specification to enable him to conduct the manufacture. And, further, in all the lamps which had been made, those who made them had the advantage of the subsequent experiments and patents which had been going on ever since November, 1879. Taking all that together, and looking to the evidence and report of Prof. Stokes, he submitted that it was sufficiently established that a workman, however intelligent and however familiar with the subject (according to the standard of knowledge in November, 1879), with the manufacture of lamps, could not have conducted the manufacture according to the process described by Mr. Edison in this patent. The learned counsel said he did not know whether he should read the report of Prof. Stokes.

Mr. JUSTICE KAY: I have read it twice.

Mr. FINLAY: Then I need not do so. Prof. Stokes deals with the manufacture of the tar putty filament, and the professor explained the difficulty of gentlemen of eminence on one side who found no difficulty in making tar putty filaments, whilst others found it impossible. The mixture of lampblack and coal tar in order to yield these results must be worked for an hour and a-half. What is the description in the patent?

"I have also discovered that carbon filaments may be used by a combination of tar and lampblack; the latter being previously laid in an enclosed crucible, and afterwards moistened until it assumes the consistency of butter."

The manipulation of an hour and a-half has the effect of making the substance into a thick putty—it becomes more like gutta percha, and is of such a consistency as would never be reached by any workman who set to work under the light of this patent. Our witnesses did their best, and these gentlemen knew how they succeeded, and they never told us, and we had not the slightest idea how they could succeed in making this. They must have had directions on this subject, and although we had not the advantage of Mr. Edison's instructions a great deal of experimenting has gone on to show how to manipulate this tar putty to yield that result.

The second point to which I desire to draw attention is to the subject of carbonisation as dealt with in Prof. Stokes's report. Prof. Stokes's report seems to show this—that with regard to the filaments made out of tar putty so manipulated, they may be carbonised in an iron box without any patent, and that they are not consumable. Some care seems to have been taken in the regulation of the temperature. There was a bit of silver introduced, and the melting of the silver wire was observable. With these precautions the use of the iron box is one of the features of the patents in March, 1880, and which certainly would not have been conveyed to the mind of any workman in this patent. With these precautions, and with a great deal of heating, it does appear that filaments made out of the tar putty may be carbonised without combustion taking place. That was a mere laboratory experiment. These were not the conditions of commercial manufacture of those filaments, and the experiments by the experts of the plaintiffs in the presence of Prof. Stokes are sufficient to justify the observation which we suggested to your lordship in the course of the case, that anything that could be done in this way was a curious experiment for the laboratory rather than a matter of practice. With regard to the filaments made out of substances other than the tar putty, it appeared from Prof. Stokes's report that packing is wanting, and he says that at Ponder's End they succeeded in carbonising without combustion with charcoal. "We were also shown the carbonisation of various fine vegetable fibres, Mexican fibre, bamboo, and others, which was done in the rectangular box packed, in one experiment, with charcoal, in another with sand, in another with kaolin. Some of the more springy fibres were kept in the horseshoe shape by elongated loops of thin copper wire, into which the ends were inserted. On opening the box after it had been fired in the furnace, and had got sufficiently cool, the fibres in each case were found to be carbonised, and not reduced to ash." However, I presume that the time is the same, and that will be half an hour. The use of charcoal packing is a matter which we say is necessary, and with regard to which Mr. Swinburne described his early experiments.

Mr. JUSTICE KAY: None of these processes could be carried on for 11 or 14 hours as it is now.

Mr. FINLAY: Exactly. What is claimed for this patent is commercial utility, and those experiments do not specify the conditions in which it is admitted that the manufacture is carried on. They themselves carried it on for 15 hours, I think.

The third point to which I call attention in Prof. Stokes's report is with regard to the coating of non-combustible material upon the filament. "We were also shown the coating of tar putty filaments with other material. The first shown was asbestos powder, used as purchased. The glass plate being covered with white blotting paper, a small quantity of the powder was put on quite thin, and the filament being laid on the paper was rolled backwards and forwards through a small space only with the upper glass tool. The finished filament was somewhat higher in colour, and on being viewed through a pocket lens was seen to be studded with particles of asbestos, between which the dark surface of the tar-putty showed itself. The other substances used were silica (in the form of kieselguhn) and kaolin. As the treatment did not differ from that used in the case of asbestos, it was not thought necessary that I should actually see it."

His lordship had seen what the results of the experiments made at Mr. Crookes's laboratory were, in the presence of Prof. Stokes. In the first place my friends may rely upon the fact that the ordinary earthenware crucible on testing with water was found to be to a certain extent porous. It was not disputed that this was the ordinary earthenware crucible. If my friend says it was necessary to point out iron he should have specified that it was something different from the ordinary crucible. It could not be expected that we were to go outside of the ordinary earthenware crucible for the purpose of obtaining the carbonisation of those filaments. The only workman who has at all spoken was produced by the plaintiff, namely, Mr. Edward Gimingham. I do not wish to go through Mr. Gimingham's history in detail, but Mr. Gimingham has received a training very far superior to that of an ordinary working man; and he cannot be considered as a specimen of the workmen of to-day, and certainly not of the workmen in 1879. He has had a very scientific experience, and the past training of Mr. Gimingham has really made him an expert of a somewhat high type; and even with that Mr. Gimingham's results do not show that these were good and workable processes. With regard to the question of carbonising generally, of course the carbonisation of filaments was absolutely unknown.

Mr. JUSTICE KAY: The carbonisation in packing.

Mr. FINLAY: I need not discuss the reference made to the question of charcoal burning and the manufacture of charcoal for the purpose of gunpowder.

Mr. JUSTICE KAY: There is no commercial proceeding in which this kind of thing was done.

Digitized by Google

Mr. FINLAY: And the workmen from their own knowledge of charcoal for any purpose before would really have been misled, because in some books, as cited by some of the plaintiffs themselves, the making of charcoal is described as a process of partial combustion. Mr. Swinburne gives an account of his early experiments at the Swan Works, at Newcastle, and if that stood alone it would be sufficient to say that the ordinary skilled workman of 1879 could not have made lamps according to the plaintiffs' processes.

The learned counsel then called attention to the numerous subsequent patents taken out by Mr. Edison himself for various processes, and Mr. Swan's subsequent patents. With reference to Mr. Swan's second patent of December, 1880, this very process of packing is described and made a point of, and when Dr. Tidy was cross-examined by his friend Mr. Aston the point of his cross-examination was that every working man would have known that packing was necessary. Now, the point made is that packing is not necessary. I do not propose to refer to the laboratory experiments made by Mr. Imray, and with reference to Mr. Gimingham's evidence I would point out that he admits that sand has never been used commercially; and I suggest the effect of the evidence is that it is only a special kind of sand of particular purity that will answer the purpose of packing at all; that for filaments under commercial circumstances it is shown that packing is absolutely necessary, and that the only packing is charcoal; and that if sand is used at all it must be under laboratory conditions and with sand of special purity. Of course it would have been necessary, except for Prof. Stokes's report, to have gone into it at much greater length as to the insufficiency of the processes; but having regard to the fact that the evidence is in your lordship's recollection, and that Prof. Stokes has made his report, I think I may conclude what I have to say with regard to the Edison part of the case.

Now I propose to say a few words with regard to the Cheesborough part of the case. The claim made by the Cheesborough patent is in respect of the process known as "flashing." In the first place I submit that there is no novelty about it, and if there be any novelty, that we have not infringed it. And there is another point which rises out of the Cheesborough patent, and it is this, that the non-conducting and non-carbonising materials vitiate this patent and vitiate a part of the process of the Edison patent. First, the claim of the Cheesborough is for the production of carbons by deposit of carbon from hydro carbon in which the conductor is being heated by the electric current, the effect being decomposition and the deposit of carbon in a particular form upon the conductor. I submit that that is a mere application to a particular purpose of the process which was described long before by Deprez and published in this country. What I am going to submit is this that if there is patentable matter at all it is merely in the use of Deprez's process for the purposes mentioned here, and all that we have done is to use Deprez's process for another purpose, therefore there is no infringement. The effect of the evidence is this, that so far as the structure of carbons goes, they are not really improved, except very occasionally; by this process, they are rather on the whole deteriorated. The point is really before your lordship, and I submit that here there is no infringement of Cheesborough's patent.

Then, further, I submit the objection with regard to the non-conducting and non-carbonising material is fatal to this patent. On these grounds I submit that the Cheesborough patent is not good.

The ATTORNEY-GENERAL (Sir R. Webster) then replied upon the whole case. He said: I propose to address your lordship upon my learned friend's objections to the Edison patent, and in the first place in regard to his main attack that Mr. Edison's specification is only a reduction of the size of the cross-section of the carbon conductor. I humbly submit to your lordship that that is absolutely concluded by the Court of Appeal. Exactly the same point was taken in the Court of Appeal in the last case. I had opened that case by stating that a bulb of glass, leading platinum wires, and a carbon conductor were old, that they were all put together in Swan's lamp exhibited in Newcastle, in December, 1878, and that so far from that having led to the discovery of Edison's patent, no single practical step was taken until after Edison had published his invention. Your lordship is in a remarkable position of advantage in this case. It is said that Mr. Swan had worked it all out for himself. It is most remarkable that, the claim having been published in December, 1878, during the whole of 1879 Mr. Swan was going wrong He says it himself. Your lordship is aware of Mr. Swan's ability and research, and throughout the whole year 1879 down to the fire in 1880 he was working away at those broken lamps. And now what is the commentary that I make upon such a state of things as that: that so far from the cleverest men being led to the Edison lamp—the most skilled man in England was working that F J B 1. And what was he doing? He was putting in coils in order to conduct the heat, he was placing something which would be inconsistent with the simple platinum wires, which were to lead direct to the platinum burner. I ask your lordship to observe that during the year 1879—and I do not think I need use much argument to excite Mr. Stearn's and Mr. Swan's distinct recollection upon the point—they were working at these failures, which they had to abandon. In 1885 Mr. Stearn was trying to make the best case for the Swan as against Edison. He described the various stages of what he had done. Mr. Swan's first lamp was in 1877 and his third lamp was in 1878. Mr. Swan's fourth lamp was July, 1880. Therefore Mr. Stearn, acting for Mr. Swan and wishing to make the fullest statement that he could, in perfectly friendly warfare, describes the Swan invention and does not describe the lamp as approximating to the Edison until the fourth lamp is made. More experiments of 1879 go no further than Mr. Swan's lamp of 1878, F J B 1. So far from leading Mr. Swan in the right path, it was leading him absolutely away. What I say is this, that Mr. Edison was the first person to tell the world that they could boldly rely upon a mere efficiency of carbon without any strengthening, and of such minute cross-sections as never occurred to anyone else.

The next point is insufficiency of specification, and I say that a more unworthy attack upon the specification has never been made by any gentlemen who have been engaged in the same pursuit. We have Mr. Sellon and practical men engaged in this matter, and they did not venture to attack this specification—they left it to the professors. I asked Mr. Crookes, "What are the main points of attack which you make?" and he said that it was "the impossibility of carbonising the filaments." I produced to him those filaments in a box, and I must say that it is difficult to speak with sufficiently moderate language to condemn such evidence as was given by the Professor. He told me that by playing tricks those filaments could be produced. He swore that they could not be produced in sand—it was an absurdity. He said by playing tricks somebody might produce those filaments, and he told your lordship, wishing your lordship to understand that he had done his best to carry out the specification, that he had reduced everything to burnt ash. What appears to be the fact?

Prof. Stokes has told your lordship that though they were carbonised in all ways, in sand and charcoal, and without any powder stuffing, he never saw any burning or reducing to ashes at all. Mr. Crookes goes through the same farce again; he uses a crucible which is so porous that the water runs out of it; and if the water would run out the hot air would go in, and in that he burns up the filaments. Your lordship will be surprised that the only witness who has come here and condemned this patent is the witness who does not see it in the crucible. You do not wonder now that Prof. Dewar—that a witness who had been accustomed to carbonisation—could not explain this. But Dr. Frankland was called on behalf of the defendants, and I cross-examined him. I asked him whether at the previous trial he had been one of the witnesses in Woodhouse and Rawson's case, and whether they had made the same attack on the specification; and "Did you say one word about the defect of carbonisation?" Well, so far from saying that it could not be done at the last trial, he produced a filament lamp, and he said that he himself had made it from Pulvermacher's specification, which is one spiral surrounding another. I said, "Were you not surprised that Crookes failed?" and he said "Yes; and I told them that I could not make them out." What do Dr. Frankland and Prof. Thompson do? Did they come and test the crucible? No, they wanted to get a failure, and having desired that, they were satisfied, without any further examination, as to what was the cause of the failure. They have never taken pains to inquire into the cause of failure. Your lordship knows from Prof. Stokes's report and from the admissions that ordinary commercial tar and lampblack were made into filaments, and these filaments have been burnt for a series of hours, and nobody pretends that a proper lamp cannot be made in this way.

I understand to-day my learned friend has suggested to your lordship that during this trial we have made some communication to Mr. Edison as to how those things are made, and, therefore, you are to assume that it is a dishonest experiment, and that your lordship is not to trust to it. What is the good of the report? You send down a perfectly intelligent gentleman, and you wish to be informed as to the result of an honest working out of the specification.

Another thing, the only reason why the defendants say that they failed is that they did not knead the putty up. I believe that the words are that the carbon filament is to be moistened and kept until it assumes the consistency of thick putty. That is exactly what has been done. It was kneaded over half an hour, and on all subsequent occasions for a few minutes. What is the state of things? The defect is the cracks.

Well, when a man kneads putty and finds it cracks he kneads it a little more. I should like to refer your lordship to that case of Handcock *v.* Goodyer, in which exactly the same objection to the manipulation of india rubber or gutta percha was taken, in which you are told to knead the india rubber, and the Court found as a fact that where the workman was told to knead india rubber he would go on a little longer trying it. It is another instance, said Sir George Jessel, of the brandy-and-water argument:—"If you find it is not strong enough add a little more." I think that these competent gentlemen, if they wished to succeed, would have kneaded the putty a little longer. It is admitted that they do succeed when they knead it sufficiently. This extraordinary compaint was made: They say we have practised another fraud upon the defendants because we have not explained to their witnesses why they have failed.

The learned ATTORNEY-GENERAL then said he must leave the case in Mr. Moulton's hands to read the cases that he himself had intended to cite.

Mr. MOULTON, Q.C., then referred to a case in the House of Lords of aniline dyes, in order to establish that it was not necessary that all the the processes described in the specification should prove equally successful or of equal commercial value. The fact was that parties had got to try them in order to determine which was the best, and if the patentee does not know at the time, it did not militate against the validity of the patent. They said that F J B 1 broke down, not because the conductors broke down, but because the joint, being the weakest part, broke down first. It was quite true that F J B 1 was a wonderful approach to the problem, but we submit that that was not a solution that had been found successful, and that was the solution described in the second claim which the plaintiffs now sued on, and probably one of the most important suggestions was that tar-putty point. Mr. Edison described a great many substances, and that common mode of joint, and it produced a firm joint electrically and mechanically. The form of the filament was an immense step. They submitted that Edison had rendered practicable that which so many had approached to, and his was one of those first and true inventions which is not vitiated or diminished by the approach that has been made by other inventors. He submitted that Mr. Edison had abundantly made it clear that he meant an exceedingly fine conductor by his patent, and it was quite impossible for him more accurately to describe that which, in his opinion—in the opinion of the world—was the essential and important

Digitized by Google

part of this discovery, namely, that there should be a carbon filament as the conductor of the incandescent lamp. At Ponder's End the mixing of the tar with the camphor, which was said to be absolutely fatal, was shown to produce lamps, and these lamps were made from hard carbon, which conducted very well indeed. If they had been submitted to the test of commercial manufacture, as to which there was so much severe criticism, it would not be of such great value. The experiment which Prof. Stokes had described was abundantly supported, and it was enough to say that those various methods all led to lamps which could burn for a more or less long life.

The learned counsel next took the case of the Otto gas engine, and he submitted that the law might be in this way—a man could not claim a patent broadly unless he was the person who made the invention.

Mr. JUSTICE KAY: If he describes three or four, some of which are perfectly useless, what then? That is the point against you.

Mr. MOULTON: I quite feel that.

Mr. JUSTICE KAY: You must take the test which Sir Frederick Bramwell put. He says that Edison made the first commercial lamp. If some of these are not commercial lamps, then it is an argument against you. A patent with so wide a claim as this patent, according to your construction, cannot be supported.

Mr. MOULTON: It is possible that a large number of them have not got those properties which would enable them to be so far commercially the best as to hold their own in the market in competition with others disclosed in the same specification. An attack has been made upon these lamps, because they use a larger amount of electricity than the lamps now in the market. According to that a patentee would invalidate his patent if he gave three or four different methods some of which were worth more than others, because the best ones would drive the others out, and the others would have no commercial utility. The House of Lords pointed out that commercial utility had not got anything to do with patent law. The question was "Is that which has been produced that which would be under circumstances which might occur useful to the public?" The fact that something else has entirely cut it out, because it is more useful, does not in the least militate against the utility in the point of value of the patent laws.

Mr. JUSTICE KAY: The argument is this, that if you have described that particular mode of making filaments—if one of your modes was one which never could be commercially useful, have you a right to say that no one else shall be able to make it commercially useful?

Mr. MOULTON: I submit that my case meets that.

Mr. JUSTICE KAY: But Lord Herschell's judgment is against you.

Mr. MOULTON: I submit that Mr. Edison was the first to publish this invention, which was the only form in which commercial lamps could be made.

Mr. JUSTICE KAY: But the publication of an idea is nothing.

Mr. MOULTON: That is my first step. I submit that on the evidence none of these lamps are shown to be such that they could not be commercial lamps. There is no process here which your lordship will see is one which will not lead to a practical lamp. Take the tar putty with the asbestos rolled around. Take the camphor and the zinc. We have proved that we have made lamps of all kinds, and the experiments at Ponder's End have proved that we have been successful. To that extent we have shown that they are all capable of leading to commercial lamps; I do not mean that now they would be able to hold the market. They would have to have the modern improvements, and our ideas of what lamps ought to do have been moulded by those modern improvements, and it is difficult now to consider what would have been sufficient to have been practicable in 1879. We have proved cases where our lamps have run from 50 to 150 hours, and that is abundant proof to make practically useful lamps.

The learned counsel, having referred to Mr. Edison's first and second patents, submitted that no extraneous evidence could be taken to give an interpretation to those patents, and that it was for his lordship to construe the document.

Mr. JUSTICE KAY: If Mr. Edison had been in the witness-box we should have asked him the question—to interpret his patent, and as he was not here I shall take his own patent as to what was in the first and what was in the second.

Mr. MOULTON: What a patentee says is not evidence. His patent is a public document, and must be construed without any extraneous evidence.

Mr. JUSTICE KAY: I must take it that no tar putty lamp was ever sold in America or England, and no lamp, according to the particular directions in this patent, was sold either in America or in England.

Mr. MOULTON: I dissent from that.

Mr. JUSTICE KAY: It was for you to prove the case; but you have not a single lamp either in England or America.

Mr. MOULTON: If your lordship excludes bamboo.

Mr. JUSTICE KAY: There is no evidence of any lamp of bamboo; and they are made on that subsequent patent.

Mr. MOULTON: This case covers that; and it is found to be the case that a better method of doing it was discovered immediately afterwards. In Bremner *v.* Livingstone they sued upon a patent on which nothing had been sold.

Mr. JUSTICE KAY: But here we have an interval of a year in which nothing is done under your patent.

Mr. MOULTON: But lamps which were produced to your lordship were actually made in January or February, 1880. That is before the complete specification comes out—it is between the provisional and complete specification. Besides, of course, in this case it was an American patentee, and, naturally, there would be some longer time; but Mr. Edison certainly sent over the lamps within a couple of months of his patent having been made. Those made in this country were made under the second claim, but by different processes. There was no claim to this particular manufacture. These were the only practical methods for carrying it out, and, if practical, it made no difference whether any were sold at all. Those were the cases with regard to utility that he intended to quote.

Mr. JUSTICE KAY: I must say that the Court has not been treated fairly in this case. I have given twenty-one days of public time to this case, and now at the last moment the reply is broken into two, and I am asked to hear two replies. This is not the mode in which the Court should be treated; and if you do not make your reply as brief as possible I shall refuse to hear you. I think the Court has very great reason to complain of the kind of treatment it has been subjected to.

Mr. MOULTON (continuing) said he wished to cite one or two cases on the sufficiency of specification. It had been said that the directions must be such that a competent workman would be able to follow them. In this case, as was sometimes the case in patents which marked stages which for the first time rendered any manufacture commercially practicable, there was at the times when they were published no trade established and no workman accustomed to the work. Supposing that they took the first telephone company. Nowadays there were people who had a regular business to make those, and it might be said that it ought to be described sufficiently to explain it to every workman. He doubted whether the law had gone so far as that. But in this case there was this admission on both sides, that there was no body of workmen engaged in this trade.

Mr. JUSTICE KAY: That is not a reason for making the specification less explicit, but more.

Mr. MOULTON: It will be addressed in this case to electricians.

Mr. JUSTICE KAY: I never heard of such a case as addressing the publications to a particular body of people.

Mr. MOULTON: In the aniline dye, it must be taken that the specification of dyeing was addressed to skilled chemists. There are terms of art which to the ordinary public would not be intelligible.

Mr. JUSTICE KAY: Then they ought to be explained.

Mr. MOULTON: With all due respect that is never held. You may pre-suppose a certain amount of skill in them.

Mr. JUSTICE KAY: There might be a patent, then, which would be utterly unintelligible addressed to electricians, to prevent the ordinary man from making a patent. That is entirely against the essence of the patent law.

Mr. MOULTON: Patents have been taken again and again to consider to whom they are addressed.

Mr. JUSTICE KAY: I quite understand that a branch of trade, as in Arkwright's case with the spinning jenny, and in the dyeing case, where there is a trade largely established, the patent may be addressed to the public in that trade. But there was no trade or occupation in existence when this patent was taken out of electric lighting.

Mr. MOULTON: The point does not arise except in the question of carbonisation. But I shall submit with regard to that that the persons who could be connected with electric lighting would be at that time electricians. There had been many attempts, but there had been no commercial success. I should submit that carbonisation is a known thing, which a great number of people would probably not have any knowledge of, and if they find the use of a term of art there it is for them to find out what that means before they applied the patent; and to such a class in 1879 as that was addressed to he should submit that there was nothing in that patent which would give rise to difficulties.

As to the question of anticipation, he submitted that there was no evidence of publication of any patent, although some of them approached very near to Edison's. F J B 1 was only an experiment, and it was not an experiment which enabled the public to make that kind of lamp, which was claimed in the plaintiffs' second claim.

As to the Cheesborough, what the plaintiffs said was what they used it for was not for the purpose of making the filament, but to make it have a proper resistance. That which was valuable in the deposit was to have the right resistance. What the defendants added was exactly what the Cheesborough did.

Mr. JUSTICE KAY: How can you support the patent as to the material?

Mr. MOULTON: With regard to the material, that was a point which came before the Court of Appeal on the last occasion. The material is novel, and it is applied by means of a process for correcting any defects, and especially producing a close-grained carbon, admirably suited for this purpose. We suggest that that material certainly never was in England before. Even if Deprez had got the material he was abroad. The papers of Deprez were published, I know, years before.

Mr. JUSTICE KAY: Do you mean to say that anybody could have followed the instructions of Deprez and patented the material?

Mr. MOULTON: I submit that he could not have followed the instructions exactly. I submit that this claim for material is really a claim for process.

Mr. JUSTICE KAY: No; he claims process separately.

Mr. MOULTON: Supposing that Deprez has not sufficiently published his process. There cannot have been a publication of material.

Mr. JUSTICE KAY: He tells you what happens if you use a certain heat passing through carbon.

Mr. MOULTON: Yes; but to obtain Cheesborough's results it must be done in a particular way. They admit that they leave it in doubt whether he puts it through the carbon or exposes it to the electric arc. No one has shown a practical method of making this carbon. Deprez would not have made it practicable. It would have been in a form absolutely useless for the purpose of illuminating conductors, because you could not have manufactured illuminating conductors out of it so as to be useful for electric lamps; we were the first to show that.

This concluded the speeches in the case.

Mr. JUSTICE KAY then announced that judgment would be reserved.

Up to the time of going to press the case had not again been mentioned in Court.

TEXT OF PROF. STOKES' REPORT.

My Lord: Having accepted the office of Independent Reporter on Experiments made in conformity with the order of the High Court of Justice in this case, of date 1st June, 1888, I have the honour to report as follows:—

The places chosen by the two parties for conducting their respective experiments were—

By the plaintiffs—The works of the Edison and Swan Company, at Ponder's End;

By the defendants—The laboratory of Mr. Crookes, at his house, 7, Kensington Park-gardens.

The two experts on the side of the plaintiffs were Prof. Dewar and Dr. Hopkinson, and those on the side of the defendants were Mr. Crookes and Prof. Silvanus Thompson. It was agreed between the two parties that the counsel on both sides should also be present.

We met at Ponder's End on June 11, 12, 14, and 15, and at Mr. Crookes's house on June 18, 19, and 21. The first process shown us at Ponder's End was the preparation of the so-called "tar putty," which formed the foundation of most of the filaments used in the lamps made in the repetition of the experiments.

The ingredients of tar putty are coal-tar and lampblack, of each of which we saw a barrel just as purchased. The coal tar is used in the state in which it is procured; the lampblack was calcined in a covered crucible placed in a brass furnace, and when taken out was preserved in stoppered bottles. I saw a good-sized earthenware crucible filled with raw lampblack, its cover luted down, and the whole put aside for the luting to dry preparatory to ignition. It was not, however, deemed necessary that I should actually see the ignition, which is a very common laboratory process; and it was agreed on both sides that the black powder used should be taken as calcined lampblack.

The putty was made by a strong-looking, youngish man named Plum. It was made on a table, on which a flat piece of hard-looking wood had been screwed down as a fixture. Some calcined lampblack was first triturated a little in a mortar, and then poured on to muslin, which was tied into a bag. A suitable quantity of coal-tar was poured on the board and dusted with charcoal, by shaking the bag over it. The two were then incorporated by using a rigid iron or steel tool, shaped much like a chisel, but not ground to a sharp edge. The charcoal was repeatedly added by small quantities at a time during the process, each fresh charge being incorporated before the next was added.

When the work had progressed some way, and the putty was beginning to get stiff, Plum evidently used considerable force. Holding the end of the tool in one hand, he strongly pressed the tool against the table with the other hand applied towards the other end of the tool, nipping a small portion of the putty lump and then drawing it out into a thin layer by a horizontal motion. The lump was thus nipped bit by bit till the whole was spread out, when the putty was scraped up with the tool, rolled into a lump by the fingers, and the process repeated.

The quantities of tar and lampblack used were not weighed; the workman judged by experience when a suitable quantity had been added. The first piece we saw made took an hour and ten minutes in the making; it was somewhere about as big as a hazel nut. When rolled into a ball the putty may be squeezed between the thumb and fore finger without cracking at the edge, and hardly blackens the fingers.

Various batches of tar putty were made during our visit, and the operation does not generally take so long as above mentioned. It was suggested that the operation might be facilitated by passing the putty between two cylinders almost in contact, which were made to revolve with very unequal velocities. This suggestion was tried next day with a slight modification, an instrument being employed which had been used for a different purpose, and which contained two brass cylinders, almost touching, movable round their axes, which were parallel, one cylinder being turned by a winch, the other left free. On trial, the putty was forced through in a sheet, with powerful shearing, inasmuch as the free cylinder was jammed by the pressure till the lump had been forced through. The putty used in the actual experiments was, however, hand-made, as heretofore.

The first process shown us in applying the tar putty was that of rolling out. Fifteen grains of the putty were weighed out by Mr. Gimingham, and given to a boy to roll. A piece of plate glass, ground on the upper surface, which lay on the table, was covered with fresh white blotting paper, which was kept from slipping by turning the edges under the glass. The weighed ball having been placed upon the paper was rolled with a tool formed of a smaller piece of plate glass, ground dull underneath, and provided with a wooden handle. This was moved backwards and forwards till the ball was rolled out into a cylinder of the prescribed length of 6in. This was then divided into lengths of 1in., and these rolled in succession just as before to a length of 6in., and divided into 1in. lengths. These were rolled out to the length of 5in. to make the final filaments, the rolling being done as before, with the exception that the under glass was used bare, and that a spatula might occasionally be used to effect a local thinning. The total length of filament, if undivided, would thus be 15ft.

The filaments prior to roasting were bent into different shapes, sometimes that of a plain, elongated horseshoe, sometimes that of a spiral.

The chamber used for the firing of the horseshoes was a rectangular box of cast iron, with a loose lid of the same material. The box was about 6in. by 3in., and 1½in. high.

It held six or seven horseshoes resting on the bottom, and was first shown us without packing, *i.e.*, with nothing but air over the filaments in the box. The lid was luted down, and set on top of the furnace to dry, and get moderately hot. It was then inserted, put into the furnace, a bit of silver wire put on the lid for a test, and the mouth of the furnace closed. After 26 minutes the furnace was opened, the silver was found to have been melted, and the box was taken out, and placed on an iron slab to cool. It was opened about 15 minutes later, and the filaments while carbonised were found not to have been burnt. They were taken out, and handed to a girl to shorten slightly to a measured length and mount. By mounting is meant attaching the ends to platinum wires, so as to secure both mechanical and electrical connection. The wires had previously been sealed into one end of a glass tube which was left open at the other.

In mounting, the girl bent the ends of the wires to the proper distance apart, to fit the width of the base of the horseshoe. She then, with a hair pencil, put on the ends of the wires small quantities of a mixture of coal-tar and lampblack, applied them to the ends of the horseshoe, and added, with the pencil, a little more of the mixture when the filament had been taken up. A minute jet of gas, blown by air, lay attached to the table, and the girl put the wire transversely into the jet, so that the heat conducted along the wire volatilised the hydro-carbons in the mixture without burning the filament. Minute additions of the mixture were made, if deemed required, to ensure contact, and were heated as before. The roasting was completed by a momentary introduction of the lump into the edge of the flame.

In a subsequent experiment one leg of a filament after mounting or partial mounting was accidentally snapped just above the carbonised mixture. It was easily mended by application of a little of the mixture, which was carbonised a little beyond or at the edge of the flame.

Another process for carbonising the junction which was shown us consisted in holding the filament at the end of the glass tube over a small disc of cast iron, which was heated from beneath by a blast of gas and air.

Naturally these carbonised filaments are tender, and require careful handling. Of the six filaments in the first box three survived, so as to be placed mounted in the hands of the glassblower for insertion into lamps.

The carbonising of the filaments in the furnace takes half an hour or so, and a contrivance was shown us for economising time by roasting three layers of horseshoe filaments in a box instead of one only. For this purpose cast-iron plates or trays are provided with short feet in the corners, and a short projection in the middle on the upper surface to lift by. There is room for two trays in a box, which thus holds 18 or 20 horseshoes. A box full of filaments thus arranged were carbonised before us.

Three other processes were shown us for carbonising the filaments in the rectangular iron box, or, rather, another process in three varieties. In this process the box instead of being left empty was filled with a packing powder of some kind. A little was first strewed on the bottom, then a layer of filaments laid on, then more packing powder put in, then another layer of filaments, and then the box was filled with the powder, closed with the lid, and luted. After drying and warming on top of the stove it was put in and fired as usual, after due time taken out, placed on the iron slab to cool, and when cool enough, or at any subsequent time, opened.

In opening, the lid was first taken off, then a sheet of paper put over, and bent over the sides; then, the paper being held against the sides of the box, the whole was turned upside down on a table, the box lifted rather gently, so as to avoid as far as might be a rush of powder, and then the heap cautiously searched for filaments.

When the box of filaments was left empty the carbonised filaments were almost always found whole, and could be easily taken out; when packing was used there seemed to be more liability to breakage, whether it were in the slipping down of the powder into a slant-sided heap, or in the subsequent search. There was usually a certain amount of loss this way.

Experiments were shown us with three kinds of packing, viz., powdered wood charcoal, kaolin, and silver sand. The process was just the same in the three cases, and in each case the filaments came out carbonised and not reduced to ash, of which I may here say once for all I saw no sign in the experiments made at Ponder's End.

The filaments of whatever kind and shape were usually connected mechanically and electrically with the platinum wires by the process already described; but we were shown also a different process as applied to horseshoe filaments. In this the ends of the filaments were connected with short platinum wires by means of little bits of tar putty rolled between the thumb and forefinger. The filaments were roasted as before in a rectangular iron box with charcoal packing. The carbonisation of the connecting bits of tar putty was thus effected simultaneously with, instead of subsequently to, that of the filaments. The platinum wires which went in bright came out dull, but the change appeared to be merely superficial, and the wires were not rendered brittle, but could be bent without breaking. The platinum ends were connected with the ends of the wires that had been sealed in glass by small brass clamps, consisting of short hollow cylinders with a side screw.

Another form of filament of which numerous examples were shown us was that of a spiral. To make spirals, the 5 inch filaments had first small bits of tar putty attached to their ends by rolling a little with the finger. These were destined merely to serve as weights for a temporary purpose. To form spirals, the weighted filaments were wound round bobbins, consisting usually of short sticks of pipeclay ware, with a strip of paper wound two or three times round the middle. Different kinds of paper were used to vary the experiment. The weighted filament having been placed astride the bobbin was coiled around it, generally with two turns, the weighted ends hanging down at the two sides of the cylinder, which was held approximately horizontal. There was room for two spirals on one bobbin.

The spirals were roasted in pots of cast iron, shaped like galley pots, about 3in. high by 2½in. wide. They were cast with upright projections inside terminating in Y's in which the ends of the bobbins rested. They had lids to fit, and the fitting was so good that luting was dispensed with except in two or three cases near the end of the experiments, when old pots were used in which the iron had sealed.

The warming and roasting were done just as before. When the pots were opened it required careful handling to separate the carbonised fila-

Digitized by Google

ments from the *débris* of the paper and take them off from the bobbins. Many came to grief in the process.

Another process shown us for the management of the spirals involved the use of a helix of thin copper wire. A suitable length of helix was taken, the spires pulled out slightly, so that they were the fiftieth of an inch or so apart, and the helix slipped over the paper-covered bobbin. The weighted filament was then rolled on so as to lie between the spires. After roasting, the carbonised spiral and copper helix were cautiously slipped off from the bobbin together, and the copper which had served as a support to the filament during this process was then dissolved off by nitric acid, and the carbonised filament was washed with water and dried.

A few filaments were tried without weights. They came out of the furnace misshapen and unsightly, but in other respects I am not aware that there was any particular difference.

Some sticks of chalk tapering a little, prepared for writing purposes, happened to be lying on the table, and one on the defendants' side suggested that they might be tried without a paper covering, as affording an unyielding support Some were cut accordingly to the proper length to rest on the Y's, and weighted filaments wound on on the bare chalk. After roasting in the furnace one came out broken, but the rest were slipped off the chalk with ease and safety.

Some tar putty filaments were rolled out a good deal finer than those above mentioned, the same or a slightly less weight of tar putty being rolled into 36 portions of 12 instead of 5 inches length. The fine filaments, measured under a microscope, proved to be about 0·0066in. diameter; allowing for the difference of length, this makes the thicker first mentioned about 0·01in. diameter. The fine filaments were cut to a suitable length, bent into horseshoes, and carbonised in the empty iron box as before, and the subsequent treatment calls for no special remark.

We were also shown the coating of tar putty filaments with other material. The first shown was asbestos powder, used as purchased. The glass plate being covered with white blotting paper, a small quantity of the powder was put on quite thin, and the filament being laid on the paper was rolled backwards and forwards through a small space only with the upper glass tool. The finished filament was somewhat lighter in colour, and on being viewed through a pocket lens was seen to be studded with particles of asbestos, between which the dark surface of the tar putty showed itself. The other substances used were silica (in the form of kieselguhr) and kaolin. As the treatment did not differ from that used in the case of asbestos, it was not thought necessary that I should actually see it.

Another material used for filaments was a mixture of tar putty with oxide of zinc; 80 grains of tar putty and 20 of oxide of zinc were weighed out and given to Plum to incorporate, which was done in a manner similar to the incorporation of the lampblack in the process of making the tar putty itself. The finished material appeared to be somewhat less plastic than the tar putty. 25 grains were rolled out, as before, and made into 36 one-inch lengths, which were rolled again to 5in. A fine thread, rubbed with coal tar, was stretched beside the filament when it had attained, or nearly so, its proper length, and the two rolled together with the upper glass tool. This, presumably, was designed to render the subsequent winding safer; but filaments of tar putty with zinc oxide were also used without thread, and thread was sometimes incorporated in plain tar putty filaments, sometimes having been previously rubbed with coal tar and sometimes not.

Another mixture we saw used was tar putty and camphor; 80 grains of tar putty were incorporated with 20 grains of camphor. The finished material seemed to be more plastic than the tar putty, and was readily rolled out except that the filaments seem rather disposed to stick to the glass, which had to be cleaned occasionally with spirit or some hydrocarbon.

We were also shown the carbonisation of various fine vegetable fibres, Mexican fibre, bamboo, and others, which was done in the rectangular box packed in one experiment with charcoal, in another with sand, in another with kaolin. Some of the more springy fibres were kept in the horseshoe shape by elongated loops of thin copper wire, into which the ends were inserted. On opening the box after it had been fired in the furnace and had got sufficiently cool, the fibres in each case were found to be carbonised, and not reduced to ash.

The operations of the glass blower in inserting the mounted filaments into the globes destined to form lamps need not, I presume, be described. The globe at the opposite end opened out into a tube, a thinned portion of which was intended to be sealed to the Sprengel exhausting pump. Each lamp was sealed in an upright position to the top of a vertical tube belonging to the system of the Sprengel, and just below the place where the lamp was sealed was a circle of small jets of gas, the hot air from which warmed the lamps during exhaustion. Asbestos muffs were put round the lamps and circle of jets, to assist in the warming. When the operator was satisfied with the amount of exhaustion, the tube was melted near the bulb, and the lamp taken off as finished.

The lamps when measured were taken into the testing room to be measured for candle-power, current, and voltage. The condition in which they were measured was that in which the current was such as to give what was judged by the eye to be about the proper brightness to the filament. I saw 19 lamps thus treated, of which, however, two gave way. The lamps were then run for duration. During the three or four hours I was there, after the running commenced, one gave way after a life of 2 hours 25 minutes. I have received a list, dated June 21st, and signed by Dr. Hopkinson, on part of the plaintiffs, and Mr. Sellon on part of the defendants, giving the results up to date; 17 lamps had died after an average life of 12·7 hours, and 12 were still running after an average run of 32·6 hours.

The experiments shown us at Mr. Crookes's laboratory related chiefly to (1) the preparation of tar putty; (2) the carbonisation of vegetable fibres and tar putty filaments in crucibles; (3) the effects of calcination in charcoal packing on the platinum ends of filaments mounted before carbonisation; (4) the effect of passing a current through a filament coated with fire clay.

1. The coal tar used had been purchased at a neighbouring shop; it seemed rather more fluid than that used at Ponder's End. The lampblack was purchased at the same shop, and had been calcined in a covered crucible for about three hours a couple of days before it was used, and when sufficiently cold had been put into a stoppered bottle. A small quantity of coal tar was taken and weighed; it weighed 82 grains. A sufficiency of calcined lampblack was put into a small bottle and weighed, in order to ascertain in the end, by difference, how much had been used in bringing the tar putty up to the proper consistence. The two were incorporated on a table, by the use of a spatula of elastic steel; one spatula was 3in. broad, the other barely an inch; the broader one was chiefly used. After about 17 minutes' work the tar putty was deemed to have attained the prescribed consistence, which was judged of by comparison with common putty, of which two lumps, of different stiffness, lay on the table. A little more lampblack had been added in this case about a minute and a-half before finishing.

Some more tar putty was made next day in a manner in the main the same, being chiefly worked on this occasion with the broad spatula. I will call the tar putty made as described in this and the preceding paragraph, "tar putty A," or simply tar putty.

Some tar putty was also made by persons on the defendants' side in imitation of the process they had seen at Ponder's End. The mixing was done on a ground glass plate, with a chisel instead of an elastic spatula, using much force in pressing down the chisel on the putty and spreading out the putty on the plate. The operators relieved one another in the work, which was continued for full an hour and a-half. I will call the putty thus made "tar putty B."

A portion of "tar putty A" was rolled into a ball, and squeezed between the thumb and fore finger. It developed cracks at the edge, and strongly blackened the fingers. The tar putty we had seen at Ponder's End on being squeezed came off from the fingers, leaving hardly any stain of lampblack. On rolling a good sized piece of "tar putty A" between the two hands so as to form a thick roll, holding the two ends of the roll with the fingers of the two hands, and drawing it out a bit, it could be pushed back for some way with hardly any force, behaving in this respect like a chain and resembling common putty, which shows the same thing, though less strikingly. The roll of tar putty on being squeezed became more shiny on the surface of the part where thickened, indicating the oozing out of a more fluid portion of the mixture.

Prof. S. Thompson rolled out a filament of tar putty. The rolling was done on ground glass by means, partly of a spatula, partly the finger, the latter being chiefly trusted to when the filament became thin. The filament was made pretty uniform by rolling any part which seemed thicker than the rest. The rolling was continued till the thickness seemed to the eye to match a figure contained in the Edison specification. The finger was dipped into lampblack to keep the tar putty from sticking.

Attempts were made to form coils with this tar putty by winding it round copper spirals formed in imitation of a drawing in the specification; but cracks were developed, and evidently the material would not hold together.

Ten grains of this tar putty were incorporated with two grains of camphor, the two being worked together with a spatula on a table. The mixture passed into the condition of a sticky fluid, and therefore some more lampblack was added and incorporated, to make it suitable for working.

Later on a filament was made from tar putty B, and wound round a copper spiral. The winding was accomplished without difficulty, and cracks were not developed, though the diameter of the spirals was considerably less than that of the bobbins that we had seen at Ponder's End. Moreover, this tar putty on being squeezed hardly soiled the fingers, and on being a good deal flattened hardly developed cracks at the edge.

2. In Mr. Crookes's laboratory, the carbonising was done in ordinary earthenware crucibles of a size to hold three or four fluid ounces. This sort of crucible is, of course, to a certain extent porous, and to test the porosity a fresh one was filled with water and set on four thicknesses of blotting paper. After an hour the paper was wetted over a circle about the size of a crown piece; after four hours the wet patch looked more than three inches in diameter.

100 pieces of vegetable filaments or strips, consisting of card, paper, dark paper, chemically prepared cellulose, wood shaving, thin cotton, thicker cotton, were put into an empty crucible, luted down, the luting dried, the warm crucible put into a furnace, where it was left for an hour and a-half. On taking out the crucible the heat was found to have been sufficient to melt copper as well as silver wire. On opening the crucible when cold nothing was found but white ash.

A similar crucible was similarly filled, with the exception that the vegetable substances were embedded in sand packing. This was fired for an hour only. On opening, a portion, believed to be the card, was found reduced to white ash; another portion was carbonised, but not reduced to white ash. It was not thought necessary to repeat the experiment, because it was not disputed that under the circumstances of the experiment the vegetable substances would have been reduced to ash had the firing been continued for a couple of hours.

A third crucible contained three tar putty horseshoes, and a fourth with platinum ends, and was packed with charcoal. On firing and opening all came out broken, and studded all over with charcoal. On attempting to clean them with a camel's hair pencil the pieces broke up still further. They were, in fact quite unmanageable.

A fourth contained a single spiral of threaded tar putty, wound on a carbon stick of 2mm. diameter. On firing and opening it was broken in taking out, and could not be separated from the core.

Digitized by Google

A fifth contained two horseshoes of camphorated tar putty. After treatment as before these were taken out whole. Most of the charcoal that stuck to them was brushed off with a camel's hair pencil.

As I have mentioned platinum ends, I may say here that the short platinum wires were attached to the ends of filaments in much the same way as we had seen at Ponder's End, only a mixture of coal tar and plumbago was used, instead of a mixture of coal tar and lampblack. When it was desired to keep the ends of a horseshoe the proper distance apart during the firing in the crucible, a thread of melting glass was passed round the platinum ends.

3. The ends of the spiral in the fourth crucible had been provided with platinum wires. These came out altered in appearance but the memorandum in my note book is "Platinum not much dulled." In one case shown us the action on the platinum ends had gone so far that the wires were rendered quite brittle; but I cannot recollect for certain whether this was one of those fired in charcoal packing during our visit or before.

4. The effect of coating a filament with an earthy substance was then tried. Fireclay was rubbed in a mortar, mixed with much water, and the finer parts separated by levigation and collected on a filter. The word "mud" will hereinafter be used to denote the material thus prepared.

Tarred thread was rolled with a little lampblack, between glass and glass, then more tar put on, and the thread rolled with lampblack, so as to form a sort of tar putty made on the thread. Four horseshoe filaments were painted with mud, allowed to dry, painted again, and so on till the diameter was two or three times that of the original filament. When dry they were fired as usual in a crucible with charcoal packing.

To mount mud-cased filaments of this kind the ends of the platinum wires sealed in glass were bent into minute rings, into which the legs of the horseshoe were inserted, and attached by the coal tar and plumbago mixture, which was in contact with both the platinum and the core of the filament; the more effectually as regards the latter if the mud coating happened to be broken off near the end of the horseshoe. The cement was heated, as usual, with attachments to carbonise it.

Two lamps were made with uncoated, and three with mud-coated horseshoes. These lamps were sealed in succession on to the Sprengel pump and exhausted. The bulbs were not heated during exhaustion; the action of the pump was continued till the gauge was sensibly level with the barometer. It was then stopped and the current allowed to pass.

Lamp No. 1 was of uncoated thread. When the current was let on a bright paint appeared at the junction of one leg with the base; an interruption of continuity was almost immediately formed, giving an arc discharge, which was known by the appearance of two very brilliant points, at first almost coincident, and in three minutes the lamp went out, showing a gap of about the 20th of an inch between the end of the leg and the base.

Lamps Nos. 2, 3, and 5, were of mud-coated, tar-puttied thread. These were exhausted in succession, the pump stopped, but the lamp not sealed off from it, but the current let pass while the bulb was still open to the gauge.

When the current was let on to No. 2 it was raised to redness. As soon as the current (0·1 ampere) and the resistance were measured, the current was increased till the lamp got to full brightness, but it died in about two minutes after the current was first let on. The bulb was discoloured.

In the case of No. 3, with a current of 4·7 amperes and resistance of 34 ohms, the horseshoe was red. There was a crack in the mud coating extending over about one-third of the whole length. The core seen through the crack was much brighter than the coating. There was a slight depression of the gauge, the bulb remained clear. The pump was worked for a bit to bring the gauge to match with the barometer nearly, and the current was then raised to 6·6 amperes. The bulb now began to be a little discoloured, and at twelve minutes from the first letting on of the current an arc discharge was formed, which was known by the formation of bright points which crept along the horseshoe. The lamp went out at nineteen minutes from first letting on the current. The gauge was found to be very sensibly depressed at the end, half an inch or so. Mr. Crookes mentioned that he had called our attention to the fact that the gauge went down before the arc was formed. I cannot speak to this from my own knowledge, as my attention was taken up with watching the changes of the filament, and making memoranda.

A lamp (No. 4) similar to No. 1 was exhausted, but on letting on the current there was a momentary spark and the lamp was destroyed.

Finally a lamp (No. 5) similar to No 2 was exhausted, and the current let on. With a current of less than 0·25 ampere the horseshoe was red, the brightness not uniform. The current was increased till an arc discharge began, when two very bright points appeared, one near the base of one leg, the other travelling up the leg. Before that the lamp had been fairly bright, but not nearly of the proper brightness. During the life of the arc the gauge went steadily down, the depression measured at the end, 11 millimetres, indicating a pressure of gas amounting to about 1·70th of an atmosphere in a volume equal to that of the bulb, *plus* that of the space above the mercury in the fall-tubes and gauge of the Sprengel, not taking account of the narrow connecting tubes.

I have the honour to be, my Lord, your obedient servant,

28th June, 1888. G. G. STOKES.

THE EASTERN TELEGRAPH COMPANY.—This company announce that subject to final audit the accounts show, after placing about £75,000 to reserve fund, a balance available for dividend sufficient to pay at the general meeting on 19th July next the fixed dividend of 3s. per share, being at the rate of 6 per cent. per annum, on the Preference shares; and a final dividend of 2s. 6d. per share, with a bonus of 2s. per share, free of income-tax, on the Ordinary shares, making, with previous payments on account, a total dividend of 6 per cent. per annum on those shares for the year ended 31st March, 1888.

REVIEWS.

Traite Elementaire d'Electricite, avec les Principales Applications (Elementary Treatise on Electricity, with its Principal Applications). By R. COLSON, Captain of Engineers. 2nd Edition, 220 pp. (Paris: Gauthier Villars.)

The title of this little work would have been more in accordance with its contents if it had been called a short summary of electrical phenomena and of their principal practical applications. The summary is very well drawn up; but we fear that it will hardly answer the purpose set forth in the preface of enabling practical men to understand the principles of the science. For example, we should hardly think it possible that a reader without previous knowledge of the subject could learn anything of the principles of the science by reading mere statements of the laws of Ohm, Joule, Lenz, Ampère, Coulomb, and others, without any information as to how they were obtained. Again, we find statements made about quantities of electricity and units of quantity, but nowhere is any proof given that what we call electricity is something which can be measured quantitatively at all.

Aide-Memoire de l'Ingenieur Electricien, 1888. By MM. G. DUCHÉ, E. MEYLAN, D. MARINOVITCH, and G. SZARVODY. (Paris: Bernard Tignol, 45, Quai de Grands-Augustins.)

This is probably the most elaborate work of reference that has hitherto been compiled for the use of electrical engineers. In the space of 420 octavo pages we find a vast amount of information both on pure science and on the industrial application of electricity. The authors evidently entertain no misgivings as to the probable mathematical attainments of those for whom the book is intended, and, on the whole, the theoretical portion seems to us more useful than the practical. Very excellent summaries are given of Frœlich's theory of the characteristic, and of Drs. J. and E. Hopkinsons' recent Paper on the magnetisation of iron. Most French writers are fully content with the teaching of M. Marcel Deprez on these points. The practical information on secondary batteries is meagre, although the theory is elucidated by means of a highly interesting differential equation. Unfortunately we have never yet come across a secondary battery whose performance was reasonably in accordance with calculation. Perhaps this is one of those things which they manage better in France. However, notwithstanding a pronounced tendency to theorise on the slenderest basis, the book will form a useful addition to the library of practical electricians.

Electricity versus Gas. By JOHN STENT. (London: Swan Sonnenschein and Co.)

This is a little sixpenny book of 80 pages, and we have no hesitation in saying that we have read it with a good deal of pleasure. The author is possessed with a most laudable enthusiasm for electric lighting, and is so genuinely and unaffectedly bewitched with the beauty and the mystery of the thing that it is impossible to be very angry when he makes a technical slip, or even when he shows a tendency to generalise, as he sometimes does, on a scale of unlimited grandeur. "Electricity," we learn on page 23, "is a product of nature, free, direct, perpetual." Gas and oil, it appears, are also products of nature, "but they are indirect, the result of vegetation, which in geologic eras was overthrown," from which the incontestable superiority of electricity is at once and for ever demonstrated. In a book of this nature, intended only to arouse an intelligent interest in electric lighting and impart a few rational ideas on the leading features of electrical science, it is needless to object to a little of this sort of writing. Nevertheless, in statements of a more avowedly technical character, the author, who "is no expert in electrical science," would have done well to get an electrician to look over the proofs, so as to keep him out of serious errors. Such a statement as that on page 44, that an arc light which is equivalent to "a group of three hundred incandescent lights must require a correspondingly large cable," is so utterly wide of the mark as to show that Mr. Stent has still to master some of the most elementary details of the subject.

The Electrician.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial and Publishing Offices
No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.
Telephone No. 2714.

All Communications to be addressed to "The Electrician," 1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to "The Electrician."

All letters intended for insertion in "The Electrician," or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.

"The Electrician" is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.

"The Electrician" is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained at all Booksellers and Newsvendors; or direct from the office as above.

SPECIAL NOTICE.

Owing to the increase in the number of pages of "The Electrician," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months.
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	... 12 6	... 24 0
„ Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	... 14 6	... 28 0
The rates for the United Kingdom remain as follows:—	4 11	... 9 9	... 19 6

TO ADVERTISERS.

"The Electrician" offers exceptional advantages to Advertisers. **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to this office.

Advertisements intended for the current issue must be handed in not later than 4 p.m. on Thursday.

TECHNICAL PRINTING.

"The Electrician" Printing and Publishing Company (Limited) *beg to inform Electricians and Electric Light Engineers that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

The Electricians' Directory.

Royal 8vo. Cloth Boards, 3s. 6d. Boards, 3s.

At the end of December in each year is issued The Electricians' Directory and Handbook. *The Directory was established in 1883, and has now attained considerable proportions. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, accompanied in many cases by Portraits.*

THE DIRECTORY FOR 1889 IS IN PREPARATION.

VOLUME XX. OF "THE ELECTRICIAN".

NOW READY. Bound in cloth, price Ten Shillings and Sixpence.
Also Cases for Binding, price Two Shillings.
Applications should be made to "The Publisher."

"THE ELECTRICAL WORLD" IN THE UNITED KINGDOM.

Arrangements have been made by which "The Electrical World" of New York can be obtained from "The Electrician" Office, 1, Salisbury-court, Fleet-street, London, E.C.

The Rate of Subscription (payable in advance), including postage, is £1. 1s. per annum to this Country and Abroad.

Single Copies of "The Electrical World" can also be obtained, price 6d. each.

The Rates for Advertisements in "The Electrical World" of New York can be obtained on application to "The Electrician" Printing and Publishing Company, Limited, as above.

"THE ELECTRICIAN" IN THE UNITED STATES.

Similarly, "The Electrician" can be obtained in America at the Offices of "The Electrical World," 168 to 177, Potter-building, New York.

"The Electrician" can also be obtained from D. Van Nostrand, *23, Murray-street, and 27, Warren-street, New York.*

The Rate of Subscription for American Subscribers (payable in advance) is $6 per annum.

ANSWERS TO CORRESPONDENTS.

G. Colebourn.—*Griscom's motor is described and illustrated in the second edition of Prof. S. P. Thompson's work on "Dynamo Electric Machinery." We may mention that a third edition of this book will be out in a few days. "The Electrical Transmission of Energy," by G. Kapp, may also be consulted on the same subject.*

C. Jacques.—*The book referred to is not out yet; it will form one of the "Specialist" series, published by Messrs. J. Whittaker and Co.*

THE EARLY HISTORY OF THE ALTERNATE-CURRENT TRANSFORMER.

The latest, and certainly not the least important, chapter in the history of the alternate-current transformer is to be found in the proceedings which are recorded in another part of this issue, and with which the attention of the High Court of Chancery has been occupied since Friday last. To comment upon a matter which at the time of writing still remains *sub judice* is very far from our intention; neither do we wish at this moment to place any interpretation of our own upon the earlier stages in the evolution of the apparatus which forms the present bone of contention. It is also quite possible, and even probable, that our knowledge of the early history of the invention may be

Digitized by Google

corrected and amplified when time has been given to compare and digest the evidence now before the Court. Nevertheless, it will, we think, conduce to a more intelligent apprehension of the case on the part of a large section of our readers if we take this opportunity to give a brief outline of the earlier patents relating to the utilisation or distribution of electrical energy in a manner more or less similar to that which was first successfully worked on a commercial scale by Messrs. GAULARD and GIBBS. Before doing so, however, we cannot omit once more to pay tribute to the remarkable zeal and energy with which, amidst almost universal discouragement, the plaintiffs in the present action forced upon the attention of the electrical world this method of electrical distribution. It is fully and cordially admitted on all sides that whatever may be the degree of merit of the particular apparatus which they adopted, and whatever may prove to be the legal status of the claims introduced into their patent specification, to Messrs. GAULARD and GIBBS belongs the honour of inducing the world at large to recognise the commercial possibilities which underlie the principle of alternate-current transformation. So much as we have already said is not in dispute.

The earliest existing patent dealing with this principle—at any rate the earliest patent to which attention has been called—is that of PAUL JABLOCHKOFF in the year 1877. M. JABLOCHKOFF describes a series of induction coils, through the primaries of which intermittent or alternating currents are to be sent, and from which secondary currents were derived for employment with the Jablochkoff candle. Perhaps the most remarkable feature in this case is the fact that in a patent dated a few months afterwards the inventor expressly states that when alternate currents are employed he prefers "to complete the magnet circuit," and he describes and illustrates an induction coil or transformer designed in accordance with this idea. For further information upon this point the reader may consult *The Electrician* of March 9, 1888, p. 481, in which the drawings in question were reproduced. Some doubt appears to have arisen as to the exact purpose which M. JABLOCHKOFF intended his induction coils to fulfil. It seems to us that a very obvious advantage attends their use in connection with the Jablochkoff system—and one which has somewhat unaccountably been overlooked. By the aid of the induction coils he was enabled to dispense with the necessity for an automatic cut-out in the event of any individual lamp failing to ignite or prematurely going out. That the same object may be better fulfilled by other means is no doubt true, but that this was the feature which commended the system to the inventor's mind we have little doubt. The second half of the year 1878 was singularly prolific in inventions—or at least in patent specifications—relating to the employment of the induction coil. The two patents which come first on the list for this year are those of C. W. HARRISON (No. 3,470, 1878), and of Sir CHARLES BRIGHT (4,219, 1878). Both are very similar in general character to that of JABLOCHKOFF, but in neither of them is the precise method of working so fully disclosed. In the latter patent there are two sentences of a somewhat ambiguous character, and to the interpretation of which it is possible to conceive that some importance may attach. These are as follows:—"The size and length of the primary wire and secondary wire coils are adapted to the number of lights employed;" and, secondly, the coils "are connected to a metallic main conductor common to all." Opinions may easily differ as to whether this implies a series or a parallel connection, or whether it includes them both.

In November of the same year provisional protection was granted to Messrs. E. EDWARDS and ALPHONSE NORMANDY for "Improvements in methods of and apparatus for producing light, heat or motive power by means of electricity" (No. 4 611, 1878). In this specification the use of induction coils traversed either by intermittent or alternating currents of electricity, and the employment of secondary induced currents is set forth in clear and fairly precise language. But whether the language is precise enough or clear enough to invalidate subsequent patents is a matter upon which we can express no opinion. With regard to the construction of the induction coils, we find that the inventors describe the apparatus as consisting of "a coil or series of coils of insulated metallic wire or ribbon (preferably surrounding a bar or wires of soft iron). . . . . Round, or adjacent to, each coil of insulated wire described we form one or more secondary coils of insulated metallic wire or ribbon, arranged so that the passage of the rapidly intermittent current of electricity, as described through the primary coil or coils, generates a corresponding current of electricity in each of the secondary coils." This patent, as we have intimated, was never carried beyond the stage of provisional protection.

Before the expiration of the year 1878 two more patents dealing with the same subject had found their way to the English Patent Office, in the form of "communications received from abroad." Mr. J. B. FULLER, of New York (No. 5,183, 1878), follows the same general idea of distribution by induction, but here for the first time we come across a regulating device. "A pivoted arm regulates the light, by strengthening or weakening the magnetic field" of the coil. The second patent, that of M. DE MERITENS (No. 5,257, 1878) is very similar to EDWARDS and NORMANDY'S, and, although tolerably complete in itself, it does not seem to contain any feature of importance which had not already been disclosed in its predecessors. With these particulars before them our readers will be able to appreciate the main points in dispute which are now being argued before Mr. Justice KEKEWICH.

PROTECTION OF BUILDINGS FROM LIGHTNING.*

BY PROF. OLIVER LODGE, D.SC., F.R.S.

(Continued from page 236.)

EXPERIMENT OF THE BYE-PATH.

We have seen that a conductor is more efficient in carrying off a discharge and preventing side-flash in proportion as its self-induction is lessened; say by spreading it out into a thin sheet, or cutting it up into a number of wires, or otherwise. But no conductor is able to prevent side-flash altogether, unless it is zigzagged to and fro so as to have practically no self-induction; in that case the side spark is nearly stopped. But so long as a conductor is straight (and a lightning conductor must, of course, be straight), so long will there be some tendency to side-flash, however thick it be made. It may be a foot or a yard thick, and yet not stop it.

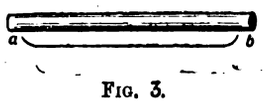

FIG. 3.

One may easily try the following experiment:—Take a yard of stout brass or copper rod an inch thick, arrange it in the path of a Leyden jar discharge, and then arrange, as a sort of bye-path or tapping circuit, some very fine wire, such as Wollaston platinum wire (Fig. 3). It may seem absurd for any portion of the discharge to leave the massive rod and take the hair-like wire by preference, especially if an air-gap exists at A or at B, or at both. Nevertheless a portion *does* choose the fine wire path, and you get a little spark at A or at B about the sixteenth of an inch long. One may vary the experiment by trying to get a shock by holding two different parts of a thick copper rod through which a discharge is passing. The mere difference of potential between conductor and earth must, of course, be avoided. It is not easy to get an appreciable shock from a few yards of very stout conductor; still it can be done. Holding two points of a stout open spiral, consisting of about five yards of No. 1 copper wire, connected to earth, a faint shock can be felt with wetted hands whenever a Leyden jar is discharged

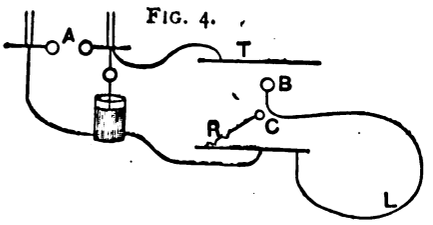
Digitized by Google

through the copper. No doubt with a very large condensor the shock would be quite noticeable, and a man touching a lightning conductor, however well earthed, might perhaps receive a shock sufficient to kill him. At all events, I should not care to try the experiment with a real lightning flash.

Experiment of the Side-Flash.

Let me illustrate the tendency to side flash by a more directly applicable looking experiment. Fig 4 shows a couple of tin plates or tea trays fixed a foot or so apart, one earthed the other insulated. They obviously represent, one a charged cloud, the other a layer of thoroughly good conducting earth. A lightning conductor, B L, is provided, L consisting of a considerable length of stout copper wire or rod. At C a possible side path is provided so that, if the flash chooses, some of it can spit off through an inch or so of air, and through an interposed resistance, R, to earth. A side flash, C, is found to occur unless the sparking distance is made too great; and the effect of increasing R is not to stop the side flash, but to weaken it. Thus, even with the liquid resistance of nearly a megohm at R, an inch spark still passes at C for every flash at B, though the C spark is now very weak.

Fig. 4.



How can this tendency to side flash be further diminished? At the end of the last lecture I hinted at a partial remedy—elasticity. To stop a pipe full of water from being burst by a blow given to the water, you will make the pipe elastic. An elastic cushion will ease off the violence of the shock of a water-ram.

Electric inertia was known by the other name of self-induction; electric "elasticity" is known by the other name of capacity. Increase the capacity—not the thickness or conducting power, but the electrostatic capacity of your conductor—and it will be able to carry off more.

This phrase, "the capacity of a conductor," when used by the old electricians, commonly signified merely its conducting power, this being the sole thing most of them thought of; but, using it in its modern signification, let us see what advantage is to be gained by increasing the capacity of a conductor—say, by connecting to its two ends the coatings of a Leyden jar.

Take the No. 18 wire round the room and use it as an alternative path, as in Fig. 1, first without a jar connected to its ends, then with a jar. Length of spark at A, 5·35-tenths of an inch; corresponding critical B spark-length:—

Iron wire without jar, 6·5;
Iron wire with jar, 5·0.

Not a very great difference. Not so great a difference as would be gained by diminishing the self-induction by flattening the wire out into foil. Still, it is in the right direction, and we see what we have to do: diminish self-induction as far as possible, and increase capacity whenever convenient. One may also try the experiment by attaching a jar to the conductor B, in Fig. 4: the side flash C is somewhat shortened.

But of an actual lightning conductor how is it possible to increase the capacity? There is no sense in surrounding it with an earth tube, because that, after all, would only act as an additional conductor, and might as well be so considered from the first. Neither does a great series of polarisable voltmeter plates seem a feasible suggestion. No; the only practicable plan is to expand it over as much surface as possible. A lead roof, for instance, affords an expansion of fair capacity which may be easily utilised; and there should be as little mere rod projection as possible before some extent of surface begins. Flat sheet for chimneys is better than round rod—it has at least *some* more capacity and much less self-induction.

For tall isolated chimneys I would suggest a collar of sheet metal round the top, and at intervals all the way down; or a warp of several thin wires instead of a single rod, joined together round the chimney by an occasional woof; or any other plan for increasing capacity and area of surface as much as possible.

Liability of Objects to be Struck.

Now try experiments on the liability of things to be struck. Is a small knob at a low elevation as liable to be struck as a large surface at a higher elevation? Is a badly conducting body as liable to be struck as a well conducting one? In other popular words, does a good conductor "attract lightning?"

* Lecture II. of the Dr. Mann lectures, delivered before the Society of Arts, March 17th, 1888.

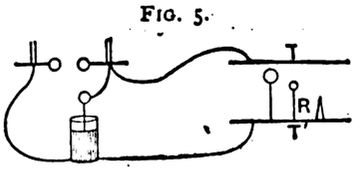
In answering this question experimentally, we must draw a careful distinction between the case of a flash occurring from an already charged surface, which has strained the air close to bursting point before any flash occurs, and the case of a flash produced by a rush of electricity into a previously uncharged conductor too hastily for it to prepare any carefully chosen path by induction. The two cases are—1st. Steady strain; 2nd. Impulsive rush. Take them separately.

First, with Steady Strain.

First an experiment on the liability of things to be struck when the air above them is in a state of steady strain gradually increased. I take the two tin plates arranged one over the other, and stand between them three conductors, one ending in a large knob, a second ending in a small knob, and the third ending in a point (Fig. 5).

The experiment consists in working up the charge of a jar attached to the top plate until discharge occurs, and in adjusting the three conductors so that they may be indiscriminately struck. One finds that the point, even when very low, prevents discharge altogether. It may, indeed, be too low to be effective; or, again, it may be insufficient to cope with the supply of electricity; but we see here the well-known function of a point—prevention of discharge. Remove or cover up the point now, and attend only to the large and small knobs. If the knobs are negative and the plate above them positive, brush discharge goes on from the knobs, and it is not easy to get a long flash; but by reversing the connections the tendency to brush is greatly lessened, and we now get flashes some three or four inches long. But always to the small knob. The small knob has to be pulled down about three times as far from the charged surface as the big knob is, before it ceases to protect the big knob; and the latter is then for the first time struck. This occurred, for instance, when the distance of the big knob from the top plate was 9, and the distance of the small one 29½, tenths of an inch. They were then either of them struck indiscriminately. If the little knob was any taller than 29½, it alone was struck.

Fig. 5.



Now what is the effect of resistance upon the protecting power of the point or small knob? Scarcely any. Instead of connecting the small knob direct to the bottom tray, connect it through the liquid megohm, R, and it gets struck just as easily as before.

Here are distance readings when they get struck with equal ease:—Large knob distance, 7·5; small knob distance, with high resistance, 22·0. The point protects both up to distance 60·0, until covered up by a thimble.

Thus the flash actually prefers to jump three times as much air, and encounter a megohm resistance, rather than take the short direct path offered by the bigger knob. The sizes of the knobs in this experiment are:—1·27 inch diameter for big knob, and ·56 inch for small knob.

Of course, the cause of this is well known. It is merely that the air breaks down at the weakest point, viz., on the surface of one of the knobs, and the tension on the small knob is much greater than that on the big one, for a given difference of potential. The fact that the discharge begins in the air above the conductor explains why it is that adding resistance—even enormous resistance—to a conductor makes no difference to the length of the spark which strikes it. The path is prepared inductively in the air, and the resistance of the path which the discharge must ultimately take makes no difference, provided it is not so nearly infinite as to prevent the free adjustment of the static charges and inductions set up as the machine is worked. But though high resistance makes no difference to the length of the spark, it does affect its noise and violence. The discharge striking the small knob has now only a soft velvety noise. Its energy, or heating effect, is much the same, but its suddenness, and, therefore, its noise and violence, are enormously lessened.

This water resistance is equivalent to a shocking bad earth; and its effect is, we see, to make the spark gentle. But it is an evident advantage to have a discharge take this quiet and manageable form. The worse a conductor is the quieter will be the flash, and, up to a certain limit, it will protect just as well apparently. Hence, surely, a bad earth is an advantage. But wait a bit; we have not yet considered the other case— the impulsive rush.

Second, with Impulsive Rush.

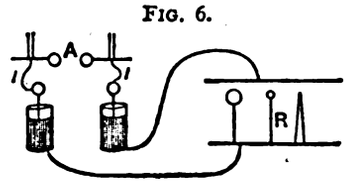
Let us now modify the experiment to try the second form of the experiment—the impulsive rush.

Fig. 6 shows the connections. There is no difference of potential between the trays up to the very instant of discharge. The jars

Digitized by Google

gradually charge up (they stand on the same wooden table), and ultimately discharge at A ; a violent rush then takes place into the two plates, and the conductors between are struck. Adjust them till they are all struck with equal ease, as before ; we find the conditions utterly different. No longer does the small knob protect the taller big knob ; no longer does the point exert any special protective influence. All three bodies—large knob, small knob, point—are equally liable to be struck if at the same height, and no one is more liable than another ; simply the highest is struck if they are at all equally conducting. It is easy to get all three struck at once. *Now* make one bad conducting, and its protective virtue is gone. Put the liquid megohm into any one of the three conductors, and that one is no longer struck. It ceases to protect the other two even if taller than they ; nay, even if it be raised so as to *touch* the top tray, thus establishing direct conducting communication of a poor kind between cloud and earth, still next to none of the flash chooses that path, and the other two conductors get struck with apparently just the same ease as before. This is the real objection to a bad earth ; it cannot protect well against these sudden rushes.

FIG. 6.

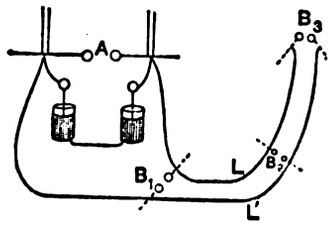


Sudden rushes are liable to occur ; the clouds spark first into one another, and then, as a sort of secondary effort or back kick, into the earth. For instance, two clouds one above the other ; the top cloud sparks into the lower, and this at once overflows to the earth. In these cases the best conducting and highest objects are struck, quite irrespective of any question of points and knobs. Points are no safeguard against these flashes, as you see. The point gets struck by a vivid flash, exactly of the same character as that which strikes one of the knobs ; it has no time to give brushes or glows ; its special efficacy in preventing discharge exists only in the case of steady action, where the path is pre-arranged by induction. In the case of these sudden rushes, the conditions determining the path of discharge are entirely different. No doubt they have to do with what is called the "impedance" of the various conductors.

EXPERIMENT OF THE RECOIL KICK.

It will have been noticed that in the experiment of Fig. 1 the spark obtained at B is longer than the spark at A. And the question arises why this should be so. Plainly, what is happening is this : the discharge at A sets up electrical oscillations, and the charge of the jars is rapidly reversed. The difference of potentials of the inner coats changes from, say, +V to nearly −V, and back again ; the difference of potential of the outer coats changes, therefore, from 0 to nearly 2V, and hence the B spark may be expected to be nearly twice as long as the A spark ; and so it is.

FIG. 7.



These electrical oscillations are of considerable interest, and have sundry practical bearings ; let us proceed to make them more conspicuous. Fig. 7 shows a couple of long leads, L and L', reaching round the room (No. 18 wire in two 95ft. lengths was actually employed), insulated from one another and from the earth, but attached to the two poles of a machine ; the machine having also a couple of Leyden jars attached to it in the customary manner when supplied by the maker. A discharger, B, can be arranged to bridge the gap between these leads, either near the machine, as B_1, or about the middle, as B_2, or at the far end, as B_3. Now, of course, sparks can be obtained either at A or at any of the B knobs, and all about the same length ; but supposing the A knobs to be brought nearer than the B knobs, the spark would be expected to occur at A only. Nevertheless, on trying the experiment, one finds that every time a spark occurs at A a longer spark occurs at B ; it is, as it were, precipitated with a rush, and the longest spark of all is obtainable at the far end, viz., at B_3.

Here are some figures, in the obtaining of which, however, for convenience of manipulation, the B length remained constant in each position, and the least length of the determining spark A was the thing observed :—

Nearest position	Spark length, A	3·20	4·15	5·12
	Corresponding spark length, B_1	3·22	4·80	6·18
Middle position	Spark length, A	1·92	2·37	2·70
	Corresponding spark length, B_2	3·22	4·80	6·18
Furthest position	Spark length, A	1·60	2·2	2·45
	Corresponding spark length, B_3	3·22	4·80	6·18

The electricity in the long wires is surging to and fro, like water in a bath when it has been tilted ; and the long spark at the far end of the wires is due to the recoil impulse or kick at the reflection of the wave. Evidently there are quantitative relations to be specified here, and there will be some best capacity of the jars corresponding to a given length of conductor, and to a given arrangement of main discharge circuit, A. The nearer the length of the conductors corresponds to a half-wave length, or some multiple of a half-wave length, of the oscillations produced by the discharging jars, the more perfect will be the synchronism between the pulses, and a longer recoil kick may be expected. The arrangement may, in fact, be compared to a resonant tube excited by a tuning fork or reed, to Melde's experiment with vibrating strings, or to any other case of forced vibration.

The following numbers will just serve to show some difference of effect caused by different sizes of jars. Using two pint jars in series, and fixing the A spark at 4·5, the B_3 spark at the far end just ceases when the knobs are pulled out to 7·8. But replacing the pint jars by gallon jars, the B_3 spark does not cease till the knobs are separated to 10·9, the corresponding spark in the position B_1 being only a trifle longer than the A spark, viz., 4·7.

It is not to be supposed, however, that by increasing the capacity of the jars still further a still better effect will be obtained ; for on replacing the two-gallon jars by the very large condenser of alternate glass and tinfoil sheets, we find the spark at B_3 fails when the knobs are only 5·9 tenths of an inch apart, the length of the A spark remaining 4·5, as before.

There is, as I say, a quantitative relation, and it is a relation which the modern theory of electricity makes known. I cannot go into it here, but I may just say that, very approximately, the wave-length of the electrical oscillation of a discharging jar is 2π times the geometric mean of the static capacity of the jar and the electromagnetic inertia of the discharger.

The capacity of the two-gallon jars in series (this being the capacity which gave the best result wth 95ft. of leads) was about ·002 microfarad, or, say, 1,800 centimetres ; hence, supposing the wave length of their discharge through the A knobs to be something like 190ft. or 200ft. (twice the length of the leads), we should calculate the self-induction of the circuit formed by the jars, short connecting wires, and A knobs, as something like five metres, which is a reasonable enough value.*

Repeating the experiment (Fig. 7) with the two-gallon jars in series, but insulated this time from the earth, a still longer spark at B_3, the far ends of the long wires can be obtained, viz., A $=4·45$, $B_3=14$; and even when the knobs of the discharger are separated beyond this distance, a brush still passes between them for every spark at A.

Removing the discharger altogether, and making the experiment in the dark, a very interesting effect is seen; the further end of each wire glows with a vivid brush light, showing the exceedingly high potential to which they are raised by the recoil. I do not see the effect with thick No. 1 wires, but with No. 18 wires it is very marked. The glow on each of the two wires is independent of the position of the other ; thus, if the connections are made so that the wires run opposite ways right round the room from the machine, the distant end being insulated, it is still the end of each furthest from the machine that glows, although they are separated from one another, for most of their length, by the whole width of the room. With the two-gallon jars the wires glow over fully three-fifths of their entire length. With jars of much larger or much smaller capacity the length of glow is conspicuously less.

Connect a small pint jar to the ends of the wires, and all these effects cease. The increase of static capacity reduces their potential below the brushing point. Arranging the jar so as to leave an air space between it and one of the wires, a spark passes into it at each A spark ; but the jar is not the least charged afterwards—proving that the spark is a double one, first in and then out of the jar, a real recoil of a reflected pulse ; hence it is also that the appearance of the brush is the same on the two wires, one is not able to say which is the positive and which the negative wire, for each is both.

EXPERIMENT OF THE SURGING CIRCUIT.

What seemed to me, when I first made it, a curious illustration of these electrical surgings or oscillations going on in a conductor which is being suddenly discharged at one end, is afforded by the following extremely simple experiment.

*Since the delivery of the lecture, a great number of quantitative observations on these lines have been made. Evidence of electro-magnetic waves 30 yards long has been obtained. I expect to get them still shorter.

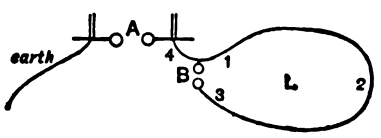
Digitized by Google

Attach one end of a long insulated wire to the machine, and connect the other pole of the machine to earth. Jars connected up also to the machine do no harm, but they are unnecessary. The wire now practically constitutes one coating of a condenser, of which the walls of the room are the outer coat. The wire is made to form a nearly closed circuit, and its further end brought within an inch or so of the near end, as at B (Fig. 8).

Under these circumstances one would at first sight say that a spark at B was absurd, for the two knobs are metallically connected through a stout conductor, which may be No. 1 wire, and not necessarily many yards long. Nevertheless, it will be found that sparks at B can be obtained quite as long, though not quite as strong, as those at A. Every A spark is accompanied by a B spark, unless, of course, the knobs are too far separated.

One may surmise that it is the static charge on the distant portion of the conductor which, having to rush toward A, prefers the short path, B, instead of the longer path *vid* the wire. But this is not the whole account of the matter, as can be shown by interposing high resistance in the conductor at various points; say at the places 1, 2, 3, or 4 (Fig. 8). Introducing a quarter of a megohm at the point 1 or at 3 weakens the B spark very much, and apparently about the same whether it be at 1 or at 3; the strength (*i.e.*, the noise and appearance) of the A spark remaining much the same. Introducing a high resistance at the point 4 weakens both the A and the B sparks. Introducing a high resistance at the point 2 leaves both sparks pretty much as strong as they were without it.

FIG. 8.



The spark at B is caused by electrical oscillation—a surging of the charge of the wire to and fro like water in a pipe. One might liken it to an elastic pipe pumped very full of water, and its end closed with spring valves. If, then, one end is suddenly opened and shut, a pulse is transmitted through the pipe, which may force open the valve at the far end and let some water escape.

It is these electrical oscillations, I doubt not, which account for the long spark obtained by the use of a "Winter's ring."

This last experiment, Fig. 8, however it may be explained, has an obvious application to the question of connecting roof gutters to lightning conductors. It is most desirable to connect them, but both ends should be connected. If only one is connected, the far end is very likely to spit off a flash.

Again, we see how, when a flash strikes a system, the electricity goes rushing and swinging about everywhere for no apparent reason, just as water might surge about in a bath or system of canals into which a mass of rock had just dropped, splashing and overflowing its banks. Just so with electricity. Bell-wires, gas-pipes, roof-gutters, conduct side-flashes in a way most puzzling to the older electricians; and thus gas may get ignited in the most unexpected places, and passengers in a train may feel a shock because a charge has struck the rails. In powder magazines it is apparent how dangerous this lawless sparking tendency may be; for even the hinge of a door may furnish opportunity for some trivial spark sufficient to ignite powder. By no means, it seems to me, should high rods be stuck up to invite a flash to such places. Build them, or line them, with connected iron, barb them all over the roof, connect them to the deep ground in many places, and I do not see what more can be done.

(To be continued.)

TEXT OF THE OFFICIAL INSTRUCTIONS FOR THE EXAMINATION OF APPARATUS ISSUED BY THE POSTAL TELEGRAPH DEPARTMENT.

All apparatus, before being issued from the depot, is tested mechanically and electrically.

MECHANICAL EXAMINATION.

The points to which the mechanical examination should be directed are as under:—

1. The apparatus must be well and strongly made in all its parts.
2. It must be accurately fitted.
3. It must be properly polished, lacquered, and finished.
4. All the adjustments must be true.
5. There must be no apparent friction in any of the moving parts.
6. The springs must be well made and properly tempered.
7. All screws must fit well and run smoothly, and such of them as are exposed to longitudinal percussion or vibration, or to any force tending to shift them, should be secured by binding nuts or other means.
8. The screws of all *new* apparatus should be of the B.A. standard screw gauge, with the exception of Stroh pattern, and slot-headed terminals, which must be of the P.O. standard terminal gauge.
9. All pivots and bearings should have sufficient end shake to prevent binding.
10. All train work should be wound up, so that the speed and regularity of running may be observed. The speed should comply with the specification as given below, and the running should be regular.
11. All moving parts should be supplied with oil at the points of friction.
12. All iron screws touching the cores of electro-magnets should be annealed and left black from that process.

Any instruments which do not comply with these requirements must be rejected.

ELECTRICAL EXAMINATION.

The following are the chief points to which the electrical examination should be directed:—

1. In a complete instrument the continuity in every lead and connection must be practically perfect; that is, there must be no appreciable resistance whatever, except that in the coils, which is specified.

The insulation of the parts electrically separated must also be practically perfect. This condition must especially be observed between the coils and the cores of all electro-magnets, and between the two wires of differentially wound instruments, which should not be approved if the insulation resistance is less than one megohm.

2. Connections and joints must be well and securely made, and where screws are used for making connections the lacquer must be removed from those surfaces on which contact depends. All contact points, studs, and plates, must be of platinum.

3. Resistances must agree within 1 per cent. of the amount specified, which is marked upon the instrument. In a few cases, which are indicated, a difference of only one-tenth per cent. is allowed.

4. The adjustments must be examined to see that the armature of the instrument has its proper range of movement between the limiting-stops, without making contact anywhere with the electro-magnet cores.

5. The apparatus must have its proper figure of merit. The figure of merit, in the case of instruments worked by a battery, is the minimum current in milliamperes with which they should work well. Thus one Daniell cell should actuate a standard relay of 400ω resistance through a total resistance (instrument, resistance coil, and battery) of 2,000ω. The current in this case would be approximately:—

$$C = \frac{1}{2000} = \cdot0005 = \cdot5 \text{ milliampere } (\gamma);$$

·5 is therefore the figure of merit of that standard relay. (In these calculations, for the sake of convenience, the electromotive force of the Daniell cell has been regarded as one volt, and the resistance of the cell, unless otherwise stated, as seven ohms. Where Leclanché cells are specified, the No. 1 form is referred to; and the electromotive force has been taken as 1·6 volt, and the resistance as 1·5ω.)

6. Nonpolarised instruments should work equally well with the current flowing in either direction through the coils. If tried with the current in only one direction, misleading results may arise from the presence of residual magnetism.

7. The proper range in the case of magneto-electric apparatus is that it must work either on short circuit or through the specified resistance without any alteration of adjustment.

8. A permanent magnet should be strong enough to support twice its own weight when suspended from a soft iron keeper placed across both its poles.

9. In all electro-magnets the armatures must be symmetrically placed with respect to the iron cores.

10. In single needle coils, galvanometers, and telephone indicators, the end of the needle from which the reading is taken should deflect in the same direction in which the current passes from terminal to terminal across the instrument, unless otherwise specified.

These points should be determined consecutively in each instrument, and every instrument that fails to comply with the requirements should be rejected.

The following are the specified resistances, ranges, and figures of merit, with other general information, for the different forms of apparatus.

Digitized by Google

A B C Apparatus.

Communicator:—
Resistance 800ω
Range: Short circuit and 7,000ω external resistance.

Indicator:—
Resistance 250ω
Range: Short circuit and 7,000ω external resistance.

Bell:—
Resistance 250ω
Range: Short circuit and 7,000ω external resistance.

[N.B.—A reliable standard set must be used for the above examination.]

Single-Needle Apparatus.

Commutators.—These must be tested for continuity between the unmarked terminal and terminal A, when the tappers are at rest. They must also be joined up on short circuit through a galvanometer to test the battery connections, and to see that they reverse properly. They must not short-circuit the battery during reversal, nor when both tappers are depressed at the same time; and, in the old form, the contact springs must be so adjusted that when the ebonite collets are fitted for universal working neither key will join the battery through to the unmarked terminal during reversal. The play at the front end of the tappers should not exceed $\frac{3}{32}$ of an inch.

Induced Coils.—The needle should rest at zero when facing north or south. It should be free when the dial is turned into any position allowed by the stop-pin, or any position between 45° right and left of the normal position if no stop-pin is fitted; and when the back pivot screw is quite home.

Resistance 200ω

Figure of merit, with which the needle should deflect to the stop-pins, 3·06γ (10 Daniell cells through 3,000ω external resistance).

Neale's Sounder.
Resistance 200ω

Figure of merit, with which the needle should deflect to the stop-pins, 3·06γ (10 Daniell cells through 3,000ω external resistance). The adjusting-spiral at full tension should be strong enough to restore the needle to zero after it has been deflected by a current of 21γ (10 Daniell cells through 200ω external resistance).

Bright's Bell.

The steel plate should be on the left hand, and the brass plate on the right hand.

Resistance of Relay 200ω
,, ,, Sounders ..... 40ω each
,, ,, Induced coil (S.N.) 200ω

Figures of merit: Relay, 3·06γ (10 Daniell cells through 3,000ω external resistance). Sounders, 67γ (5 Daniel cells without external resistance). Induced coil, 3·06γ (10 Daniell cells through 3,000ω external resistance), with which the needle should deflect to the stop-pins. *See* general remarks under S.N. Induced Coils.

Double Sounder.

The steel plate should be on the left hand, and the brass plate on the right hand. The armatures of the sounders should not touch the cores when the local current is on. The outside ends of the sounder coils should be of strong wire—24 mils. in diameter—to prevent breakage.

Resistance of relay (200ω+200ω parallel) 100ω
,, ,, sounders ..... 20ω each.

Figures of merit: Relay, 3·15γ (10 Daniell cells through 3,000ω external resistance). Sounders: 71γ (2 large Daniell cells—each of 4ω resistance—without external resistance).

Galvanometers.

Each galvanometer should give equal deflections on opposite sides of zero. In vertical galvanometers the pointer should rest at zero when facing north or south.

Ordinary (S.C.).—In galvanometers of this form fitted with revolving dials, the needle should be free with the dial turned into any position allowed by the stop-pin, or any position between 45° right and left of the normal position if no stop-pin is fitted; and when the back pivot screw is quite home.

Resistance ..... 30ω *

Figure of merit, with which the needle should deflect to the stop-pins, 9·3γ (1 Daniell cell through 70ω external resistance).

Differential.—The coils should be differential with the needle in any position between 30° right and left of zero, with 50 Daniell cells without external resistance, care being taken that the current is passed through the coils in both directions. In those galvanometers into which switches are fitted the short-circuiting action should be proved.

Resistance of differential coils ..... 50ω each
,, ,, extra coil (if provided) 8ω

Figures of merit, with which the needle should deflect equally on each side not less than 40° nor more than 50°. Each differential coil, 17·5γ (1 Daniell cell—of 7ω resistance—without external resistance). Extra coil, 128γ (5 large Daniell cells through a total resistance of 39ω).

Horizontal.
Resistance 800ω

Figure of merit, with which the needle should deflect not less than 25°, ·048γ (1 Daniell cell through 20,000ω external resistance). The oscillations of the needle in coming to rest should be not less than 10.

Q. and I. Detector:—
Resistance of intensity coil 100ω
,, ,, quantity coil ..... ·2 ω
,, ,, ,, ,, (shunted) ..... ·04ω (about)

Figures of merit: Intensity coil should give deflections of not less than 40° nor more than 50° with 9·3γ (1 Daniell cell—of 7ω resistance—without external resistance). Quantity coil should give deflections of not less than 20° nor more than 30° with 139γ (1 Daniell cell—of 7ω resistance—without external resistance). The "quantity" deflections should fall to one-fifth of their original amount when the shunt is applied.

Test Box Detector (old form.)—The connection and insulation of the terminals and switch plates should be tested by battery and galvanometer.

Resistance 200ω

Figure of merit, with which the needle should deflect not less than 20° nor more than 30°, 3·06γ (10 Daniell cells through 3,000ω external resistance).

Test Box Detector (new form)—
Resistance of "Line coil" 100ω
,, ,, "Daniell and Leclanché" coil ..... ·2ω
,, ,, "Bichromate" coil ..... ·1ω

Figures of merit: Line coil—Should give deflections of not less than 40° nor more than 60° with 9·3γ (1 Daniell cell—of 7ω resistance—without external resistance.) Daniell and Leclanché coil: Should give deflections of not less than 20° nor more than 30° with 139γ (1 Daniell cell—of 7ω resistance—without external resistance). Bichromate coil: Should give deflections of one-fifth the amount of those given by the Daniell and Leclanché coil, with 141γ (1 Daniell cell—of 7ω resistance—without external resistance).

Tangent.—The slot in the stalk of the controlling magnet must be perfectly straight so that the magnet shall not turn when raised or lowered. The key should short-circuit the coil when depressed.

Resistance of long coil—both plugs out 1,070ω
,, ,, left-hand plug in 320ω
,, ,, both plugs in *32
,, short coils—outer terminals ..... ·13ω

Figures of merit: the examiner facing west, with the galvanometer placed so that the terminals in use are on the side nearest to him; the controlling magnet also being removed from the instrument whilst the tests are being made. (Should the examiner face east, all deflections will be reversed.) Long coil.—Both plugs being out, should give deflections of not less than 25° nor more than 35° with 1 Daniell cell without external resistance. The oscillations of the needle after these deflections should not be less than 10. Short coils.—Should give the following deflections with 1 Daniell cell through a total resistance of 10ω:—C to right hand and Z to centre terminal, about 10 tangent divisions to the *right*. C to right hand and Z to left hand terminal, about 30 tangent divisions to the *left*. C to centre and Z to the left hand terminal, about 40 tangent divisions to the *left*.

Keys.

The play of keys (other than S.C.) should be $\frac{1}{16}$th of an inch at the front end of the lever. The freedom of the lever should be such that the front end will fall by its own weight when the antagonistic spring is unhitched. New platinum contact points should project $\frac{1}{16}$th of an inch from the studs. Contact springs must be properly hardened and tempered—a matter of special importance in the case of increment keys. The connections and insulation of all keys should be proved by battery and galvanometer. Double current keys must not short-circuit the battery during reversal. Reversing keys must short-circuit the battery during reversal, but for the shortest possible time. In all keys with switches a test must be made to prove that the switch when moving from side to side would not join the battery through to the receiving apparatus.

* This resistance must be exactly one-tenth of that obtained when the left hand plug only is in.

Digitized by Google

Relays.

The tongues in those relays having two should be in line, and should be free in their pivot holes, so that when lifted they will drop back into their proper position again. The screw adjustment must be made to turn righthanded for marking and lefthanded for spacing. The spiral joining the axle to the frame should be of 4 mils soft uncovered copper wire. Every double-wound relay should be differential (when adjusted for its figure of merit) with 50 Daniell cells without external resistance, care being taken that the current is passed through the coils in both directions. The following working tests should be made with the coils in series, and at key speed, unless otherwise specified, a sounder being used to prove the local connections.

Post Office Standard A—

Resistance ..... 200ω+200ω

Figure of merit: ·5γ (5 Daniell cells through 9,500ω external resistance).

Post Office Standard B—

Resistance ..... 100ω+100

Figures of merit: For working sounder at key speed, ·5γ (5 Daniel cells through 9,700ω external resistance). For repeating at the rate of 400 words per minute, 17·5γ (30 Daniell cells through 1,300ω external resistance, a condenser of 2 m.f. capacity being joined across 800ω of the external resistance). In neutral relays (P.O.S. with spiral springs), the springs should be removed from the contact-arm whilst the tests are made. The pivot must not be raised from the plate when the spirals with their fullest tension on are holding the contact-arm in the neutral position. Dimensions of spiral: 10 turns, exclusive of loops, of 15 mils brass wire for standard "A," and German silver for standard "B," outside diameter of spiral ⅛ of an inch.

Post Office Standard C.:—

Resistance 1,200ω

Figure of merit, ·098γ (1 Daniell cell through 9,000ω external resistance).

Nonpolarised Relay B.:—

Resistance ..... 200ω+200ω

Figure of merit, 6γ (20 Daniell cells though 2,800ω external resistance). The adjusting spiral when fully extended should be strong enough to prevent the tongues from being attracted when a current of 12·2γ (20 Daniell cells through 1,100ω external resistance), is flowing through the coils, the tongues being at the same distance from the poles as for the figure of merit test.

Nonpolarised Relay B. (large):—

Resistance ..... 100ω+100ω

Figures of merit.—For working sounder at key speed, 6γ (20 Daniell cells through 3,000ω external resistance). For closing an electro-magnetic switch whilst a transmitter is sending reversals at the rate of 400 words per minute, 17·5γ (20 Daniell cells through 800ω external resistance, a condenser of 2 M.F. capacity being joined across the external resistance).

Siemens':—

Resistance ..... 200ω+200ω

Figure of merit, 1·13γ (5 Daniell cells through 4,000ω external resistance).

Stroh's (new form):—

Resistance 1,200ω

Figure of merit ·098γ (1 Daniell cell through 9,000ω external resistance).

The adjusting spiral should be of 7 mils brass wire; one tenth of an inch in diameter; and not less than one inch long including the loops. The pin in the tongue to which the spiral is attached must be not more than ⅜ths of an inch from the pivot.

Telephone Relay (*see* under Telephone Apparatus).

Switches.

Must make good contact in their various positions. All pegs must fit properly. The standard space below the point of a peg is ⅛ of an inch. All levers and springs must be properly insulated from each other, and rivets must be such as not to give way with constant use.

Electro-Magnetic Switches (*see* under Repeaters).

Telephone Switches (*see* under Telephone Apparatus).

Sounders.

In Pony sounders A and B the lacquer should be removed from the ends of the limiting screws, and from those parts of the lever or frame against which they strike. The limiting-screws should be flat at the end not pointed.

Pony Sounder A:—

Resistance 40ω

Figure of merit, 67γ (5 Daniell cells without external resistance).

Pony Sounder B:—

Resistance. { Electro-magnet..... 20ω / Shunt (German silver wire).. 500ω } 19·2ω

Figure of merit, 92γ (5 Daniell cells without external resistance).

GAULARD AND GIBBS v. FERRANTI.

In the Chancery Division of the High Court of Justice, on Friday, before Mr. Justice Kekewich, the petition *in re* Gaulard and Gibbs patent came on for hearing. Messrs. Gaulard and Gibbs claim to be the inventors and patentees of a system of distributing electricity by means of secondary or induced currents, and the petitioner, Mr. Ferranti, who is also the patentee of electrical apparatus, seeks to have Messrs. Gaulard and Gibbs's patent revoked on three grounds, namely—(1) want of novelty, (2) lack of utility, and (3) that it was anticipated. Sir Henry James, Q.C., M.P., Mr. Theodore Aston, Q.C, and Mr. Cutter appeared for Messrs. Gaulard and Gibbs; and Sir Horace Davey, Q.C., Mr. Fletcher Moulton, Q.C, and Mr. Pike for Mr. Ferranti.

Sir HENRY JAMES, in opening the case, said the petition was presented under the 26th section of the Act of 1883 by a person named Ferranti. Ferranti was not a person mentioned among the different classes of people entitled to petition under the Act, but he had obtained the *fiat* of the Attorney-General, and was therefore entitled to proceed. He had now to state the facts. The patent which was sought to be revoked was dated the 13th September, 1882, and was granted to Lucien Gaulard and John Dixon Gibbs, who now had it in their possession. The subject matter of this patent was a process of distributing electricity for lighting purposes. As his lordship was doubtless aware, the lighting of public places and large buildings by this agency was of great utility, but at the same time was a matter of great difficulty. Previously to the year 1882, and certainly during the years 1878 and 1879, the manner of the delivery of this electric agency had proved comparatively a failure. With the arc system of lighting there proved to be a want of constancy in delivery, and if the current ceased to run from either of the pieces of charcoal employed in the lamp there was a cessation of the current, not only in that particular burner but throughout the whole circuit. In all the patents obtained he thought his lordship would find none of them produced a commercial result, and that not a single invention was brought into practical use. The first thing sought was to obtain the delivery of the light in such a condition that it would be constant and not intermittent; and then came a problem which had not yet been entirely solved, namely, the supply of the electricity with such economy that it might be used as a successful competitor against gas. In order to effect that they had to deliver the electric light at the place of its use—that was, at the burner—under such conditions of force that it should not be too strong or too weak. They would find that for a certain time electricity was delivered by a primary current carried direct to the burner, and the result was that the distance over which the electricity could be carried was very limited. They would not discuss the number of yards it could be carried; but no one would say that the current could be carried under such circumstances more than half a mile. His lordship would therefore find that in the past times of electricity an attempt was made—an attempt which had proved a commercial and an actual failure—by means of the direct agency of electricity with one current and one force alone from the generating machine to the burner's mouth. The great point on which he laid great stress was that this system never did succeed and never could have succeeded. Men of the greatest ingenuity employed the greatest scientific research upon this subject, and attempts were no doubt made, first in one direction and then in another, to obtain greater economy and better regulation of the electricity at the point of its delivery, and to secure a greater power of delivery over longer distances than could be obtained by one direct simple mode of carrying the electricity. As he had said, none of these attempts succeeded, but in 1882 Messrs. Gaulard and Gibbs produced and made known to the world an invention to which he (Sir Henry James) would have to call his lordship's attention, and which could be worked, and had been worked, successfully. Whilst he had pointed out that probably the extreme length to which, under the old system, a current could be carried for lighting purposes was half a mile, the current under the method invented by Messrs. Gaulard and Gibbs could be carried to the extent of fifty miles. Whether it could be carried for fifty miles for all purposes, and under all circumstances, he could not say, but they would find that under all the conditions necessary for distributing electricity for actual use it could be carried to a distance approximating on fifty miles—at all events, to thirty or forty miles, and in such a way, and at such a cost, as to be a commercial success. When he said that it could be distributed to the extent of fifty miles, that was not a fanciful estimate, or a distribution under fanciful circumstances. In the year 1884 there was an exhibition of lighting apparatus at Turin, and advertise-

Digitized by Google

ments were sent forth to the whole world, inviting people to exhibit apparatus there. From all points of the compass men brought their inventions, and Messrs. Gaulard and Gibbs, among the rest, shewed their apparatus. They did at the exhibition circulate electricity to the extent of fifty miles for lighting purposes, and from all competitors they carried off the money prize and the gold medal. That was an acknowledgment that their invention was a success ; and he would now tell the court what it was these gentlemen had invented. There was first of all a dynamo machine, and passing from the left-hand side of the centre was a wire. That was the conductor, and was the main line of the system. It passed round and re-entered the dynamo, completed the circuit, and produced what was known as an alternating current. In old times the current of electricity was direct, and they would have tapped their main wire, and so have conducted the current from the dynamo to the burners. That would have furnished a certain amount of electric power, but it would have required so much force behind it that it would have been expended before it had gone many hundreds of yards. There were two kinds of wires which might have been used. If a wire of large diameter—say, a foot—were employed, they would in such an agent obtain very little resistance to the electricity ; but if they employed a very small conducting wire, as, for instance, one-eighth of an inch, they would get a very large resistance relative to the amount of electricity which went through. If, therefore, under the old system it was desired to send the electricity a long distance they could only do it by lessening the resistance. Therefore it would be necessary to employ a wire of very large diameter and involving such enormous expense as to be prohibitory. What was required was a wire of small diameter, and yet in that small wire they found such tremendous resistance that that also failed. The result was that people had to set themselves to work to find out how to overcome this prohibitory resistance at such a cost as would enable electric lighting to be economically carried out. The gentlemen who opposed this petition set themselves to work and produced this patent. First, they had to secure a small main wire, and that they had done. They had secured the use of a wire as small, he believed, as one-sixth of an inch, and then they got rid of what had always previously existed, namely, the direct communication between the dynamo and the burner's mouth. They employed what were known as secondary generators, and the wires that conducted the electricity after it had been brought into tension passed over this deliverer to the burner's mouth. In the old system the electricity passed direct from the dynamo to the burner's mouth, and therefore they had a high pressure throughout. Then came into play a system of what was recognised and known as secondary currents. As this great and powerful agent of electricity passed through a wire, if they put another wire near it there was such sympathy between the two wires that the electricity in the primary wire would display itself in a diluted form in the approximate wire, and sympathetically would act in that approximate wire. If, for instance, they got 2,000 volts in the primary wire, they would find it diminished in the secondary current in their system to 300 or 400 volts. His lordship would at once see the advantage of this. Directly they brought the electric current into contact with one of these secondary conductors they placed within the secondary conductor the exact amount of force required to carry the electricity on to the burner. They therefore got a small amount of force and a small amount of expenditure as the result of the dilution of the current in the secondary conductor, and they could regulate it to get exactly the force which was required. These two objects had been accomplished. Amongst other places where this useful and practical invention was employed was at the Grosvenor Gallery. The Grosvenor Gallery Company obtained the right under agreement to use the patentee's method for distributing electricity for the purpose of lighting the building. They had the right to use this invention ; they were bound to give an account of what they used, and to pay for it, and were not allowed to dispute the validity of the patent. They without a doubt said from time to time through their engineers that the system was not a perfect system, and the view of the patentees was that it had not been used in a perfect manner. But this occurred : the company employed to work this system a person of the name of Ferranti. Mr. Ferranti became perfectly acquainted with the patent obtained by Messrs. Gaulard and Gibbs, and with all that was done under it, and in December, 1885, three years after the date of Messrs. Gaulard and Gibbs' patent he obtained a patent of his own. He was not going to discuss Mr. Ferranti's patent, but its object was to accomplish the same results as that of Messrs. Gaulard and Gibbs. The Grosvenor Gallery Company were really the petitioners in this case. They took possession of this patent and used it. It was whilst he was under their fostering care, whilst he was their servant, that Ferranti acquired command of Messrs. Gaulard and Gibbs's patent. He learnt enough to enable him to frame a patent of his own, and got the Grosvenor Gallery Company to say, "We have Ferranti's patent ; we do not under Clause 2 of the agreement feel we have any obligation to burn your lights, and we set up Ferranti's patent against yours." Mr. Ferranti, who was a subsequent patentee, now petitioned to have the patent of Messrs. Gaulard and Gibbs set on one side. While I cannot say that this petition cannot lie, I do say that Mr. Ferranti, to succeed, must prove his case up to the very hilt. Without waiting for Messrs. Gaulard and Gibbs to attempt to enforce their patent Mr. Ferranti brought this petition, and said he would show that Messrs. Gaulard and Gibbs's patent was for all purposes and in every particular a bad patent. If he (Sir H. James) could show that this patent was good for any purpose he should submit that it was a good patent. He was not putting it to the Court that the patentees had invented any new principle. The dynamo was old and the main wire was old, but this was a patent got on account of a combination of several things which might be old, but which had produced results which had never been produced until the patent came into existence—results of substance, of great commercial utility and of a successful practical character.

The first witness called on behalf of Messrs. Gaulard and Gibbs was

Dr. HOPKINSON, F.R.S., who, examined by Mr. Aston, said that electricity, in its application to practical purposes, was usually obtained by the application of mechanical power working in conjunction with a dynamo machine. The direct-action dynamo was the one most commonly in use prior to the date of the patent. From the time of Faraday downwards the production of induced currents in a wire laid side by side with a main wire connected with a battery was well known. Prior to 1882 the use of induction coils for the purpose of utilising electricity was well known, and had been for many years. The passage of electricity was analogous to the passage of water through a pipe. The pressure of the water was represented by tension in the electricity, and the quantity of the water was represented by the size of the electric current. If it were desired to send electricity a considerable distance it would be necessary to have either very large conductors or a very high tension, and these difficulties prevented the application of a direct-acting current through a main wire or a long circuit. From 1879 to 1882 many attempts were made to apply upon a long main wire of small diameter installations of electric lighting at various distances. He did not know that any of these systems were attended with a great amount of success, and certainly neither of them depended upon an induced current excited on a local station by the presence in the main wire of an electric current in a state of high tension. He had examined the specifications of Messrs. Gaulard and Gibbs' patent. It was perfectly intelligible to competent electricians and fairly described a system of distributing electricity for lighting purposes. He had examined the various specifications put in by the petitioners, and not one of them described a system of distributing electricity which would supply the desideratum which existed between 1879 and 1882. Witness had made himself acquainted with the specification of Messrs. Gaulard and Gibbs's patent of September 13th, 1882. It was described as a "new system of distributing electricity for the production of light by means of incandescent or other lamps." This system consisted of the employment of an alternating current produced by electro dynamos, and determining by its passage through a number of electrical generators of special construction, the formation of induced currents, of which the quality and the value depended on the construction of the secondary coils in the electrical generators. The electricity was supplied by an alternating dynamo. The main conducting wire went round and passed in at the primary circuit of one of the secondary generators. It then passed through the primary circuit, and went on to the primary circuit of the second wire, and so on through the whole series, and then back again to the right-hand terminal of the dynamo machine. When, therefore, the dynamo machine worked, there would be induced currents in the armature of the machine of an alternating character. These currents circulated through the whole of the external surface, and through all the primaries of the secondary generator. Every secondary wire in every secondary generator would be a source of supply of electrical power, which might be used for the purpose of lighting lamps.

What would be the character of the current induced in the secondary coil constructed in the way you have described, and supplied from an alternating dynamo at high tension?—The current in the secondary coil would be of comparatively low tension as compared with the tension of the whole circuit.

Would the use of that diminished tension be beneficial for the application of the current locally, for a series of lamps, or otherwise?—It would be beneficial.

Witness explained that if a greater tension than 100 volts were used for incandescent lamps the lamps would be broken. In transmitting the energy to the dynamo machine, if the distance were great, the conductor would have to be very large in order to get the tension they desired for their lamps. By Messrs. Gaulard and Gibbs's invention they were relieved of that difficulty, because they could get whatever tension they pleased in the secondary circuits for the lamps, and were able, on the other hand, to have almost any tension they pleased for the primary circuit. The three co-operating elements of Messrs. Gaulard and Gibbs's patent which distinguished it from other systems were an alternating dynamo supplying a main wire with a current at high tension, and a secondary generator such as he had described. He did not find those three elements described in any one of prior specifications set forth in the particulars of objection. He first saw the system invented by the patentees at work at the Edgware-road Station of the Underground Railway, and at Mr. Gibbs's request he examined and reported upon the apparatus. The length of the main wire at work there was something about fifteen miles. There were about 2,000 volts of electricity passing over the primary coil, and when he measured the power between the terminals of one of the secondary generators he found there was a waste only of 13 per cent. He expected from his experience a very much larger waste. That was in the early part of 1884. He then satisfied himself that the system was at work and was working satisfactorily. Prior to that time he had never seen such results produced in that way. It was a matter of common notoriety in the electrical world now that this method was largely used in the United States. The original specification fairly represented the system which it professed to describe.

Cross-examined by Mr. FLETCHER MOULTON: Can you point to anything in the specification which describes the kind of secondary generator used by the patentees?—They do not do anything further than describe secondary generators, which would have answered their purpose. It was, continued the witness, well known prior to the date of the patent that the primary and secondary coils of the Ruhmkorff coil were interchangeable, and it was known, too, that it was possible to change tension to quantity and quantity to tension by the use of the induction coil. So far as the patentees' coil was concerned, it was an ordinary Ruhmkorff coil with six wires.

Was it common knowledge at the date of the patent that it was possible to distribute electricity by sending an alternating current through induction coils?—It had been suggested.

What is there beyond that in the first clause of this patent?—The spe

Digitized by Google

cification states that the alternating current is to be generated by an alternating dynamo machine, and the alternating current must be of high tension ; moreover, the secondary generators have divided cores.

Does it make the slightest difference whether an alternating current is got from an alternating machine or not ?—It makes a great deal of difference in the cost. The alternating-current machine is older than the patent.

Now, the divided cores were quite common. If you placed any induction coil on a high tension dynamo, the tension is at your choice ?—Within limits.

Is there a single word or passage in the specification which tells the public they are to have a secondary current with a lower tension than the primary current ?—It is implied in the size of the wires through which you are to pass the secondary current.

Can you show in any place where the patentee points out how the tension in the secondary current is to be lower than in the primary current ?—No, I cannot.

The specifications of Jablochkoff's patent of 1877 shows a means of distributing electricity by means of alternating currents and secondary generators ?—It involves the use of lamps of a very high tension.

Was not Jablochkoff's process a perfectly applicable one at that day ?—Not as described in the specification.

But the lamp is no portion of the plaintiff's claim ?—No.

It has nothing whatever to do with the use to which you put the electricity when it is distributed ?—No. But Jablochkoff's is not an alternating current at high tension.

Why could it not have been used at high tension ?—It could, but he does not disclose it.

Do you mean to say that high tension in the primary would not assist in getting high tension in the lamps ?—You must have your tension suitable to your induction coils.

Do you mean to suggest that any ordinary electrical workman who took the Jablochkoff apparatus and used it in any ordinary induction coil would not have got a practical distribution of electricity ?—If he should use the Ruhmkorff coils he would do better, but he would very likely have done what Jablochkoff did—use an unsuitable secondary generator.

The case was then adjourned till Monday.

Monday, July 2.

On the resumption of the Court on Monday,

Dr. HOPKINSON, cross-examined by Mr. FLETCHER MOULTON, continued : In the specification of Jablochkoff's second patent there was a description of an electro-magnet. There would be no divided core in that if used for a continuous current.

But if you put a coil on it and use it as an induction coil the importance of a divided core would come in ?—Yes.

All that was thoroughly well known at the time ?—Known to a great many people, no doubt.

Would not any competent maker of electrical instruments, in following out the directions of Jablochkoff's second claim, use a wire core ?—I do not think they would ; some did, some did not.

Do you mean to say that a person in 1882 who was told to put a core to an induction coil would not necessarily have put a wire ?—Not necessarily.

Can you tell me a single coil in the market in any of the more carefully constructed instruments in 1882 in which the core was not divided ?—Undivided cores were used in some telephones, I think.

Can you show anything in this specification which limits plaintiff's first claim to the use of machines with divided cores ?—I can show you that he d escribes it as a machine with divided cores in two cases.

Apart from the question of the fineness or the coarseness of the wire, is not the method described in Du Moncel's "Exposé" the same as that plaintiff proposed to use ?—Yes; but without the high-tension primary.

Then apart from the size of the wire and the tension, Du Moncel's description would be an anticipation of the plaintiff's first claim ?—No, an anticipation of the third claim, as an instrument.

Du Moncel uses an alternating machine and a coil, which would have a wire core ?—Yes.

Then, except for the coarseness of the wire and the high tension, this would be an anticipation of the plaintiff's first claim ?—It is not for me to say whether it is an anticipation.

But Du Moncel describes a number of induction coils on the same circuit, and worked by an increase of tension ?—Yes.

Have you any doubt that this is an accurate description of what Jablochkoff actually did ?—I see no reason to doubt it.

And according to this Jablochkoff, by means of an alternating machine and a current passing through induction coils, obtained for distribution electricity for the purpose of lighting, the lights being placed on the secondary circuits of these induction coils ?—Yes, that is so.

It does not say what the dimensions of the induction coils were, and it does not restrict it in any way to any tension ?—He says the spark was scarcely more than two millimetres in length. That would be upwards of 2,000 volts.

Was that a suitable potential for using with his lamps ?—No doubt.

Suppose a person wanted to use the plaintiff's system for one of the lamps of the class Jablochkoff was using, he would have to have similar coils ?—Substantially ; but I am not aware the plaintiffs proposed to apply it to any particular kind of lamp.

Can you point out anything different between Jablochkoff's system and plaintiff's system ?—Jablochkoff had a different motive power, and proposed to work with a high tension.

Can you show anything in the plaintiff's specification which shows the light he was going to use required a high tension, or a low tension in the secondary ?—No, except that he had a light and a motive power which were available for low tension.

Where does the plaintiff say the tension of his secondary circuit ought to be low ?—He does not actually say so anywhere ; but it is implied by what I have told you.

With the exception that Sir Charles Bright states in his specification that the primary current is to have a high tension, is there any distinction between Bright's description and the plaintiff's first claim ?—Bright says nothing about the construction of his cores, and he does not say you are to use an alternating current, but rather inclines to a continuous current, and he uses a magneto-electric machine.

But a magneto-electric machine produced an alternating current as often as not ?—The inventor does not say which he proposes to use.

If you had a continuous current you would want an interruption ; if you had not a continuous current you would not want one ?—Yes ; and that makes a great deal of difference.

Now in the description of Johnson and De Meritens' method there is a distinct statement that the cores of the primary are to be made of bundles of fine wire ?—Yes, but they spoil the effect of it by putting in a solid piece of iron at the end (laughter).

Do you suggest this would not work well ?—No ; it would not work well.

Would it not distribute a light over fifty bobbins ?—No doubt over a considerable number of bobbins, but there would be a great waste of power in the apparatus. You may be perfectly certain it would not work successfully. Apart from the faulty construction of the secondary generator, and that the high tension is not disclosed, I do not know that I can point out any difference between De Meritens' system and the system described by the plaintiff in his first claim.

Witness, continuing, said he did not think Messrs. Edward and Normandy's system would work successfully, nor did he think the description which they furnished would lead one to work out Gaulard and Gibbs's system. He had looked also at Lake's specification, and he did not think Lake's apparatus would work at all. The inventor proposed to put secondary coils round the poles, which would result in waste of power.

Lake says any form of magnet can be used if the local coils are placed round the poles. Were there not many forms of magnet in which induction coils were placed round the poles, and which would have answered exceedingly well ?—There are none which occur to me. From the construction of the apparatus, witness thought it a reasonable inference that solid cores were used. There was nothing, in witness's opinion, in Deprez's specification which would lead one to construct Messrs. Gaulard and Gibbs' apparatus, and the same remark applied to the description of an instrument in the *Electrical Review*. He did not think there was anything in the last-mentioned apparatus which would obviate Foucault currents, and he doubted if the core was made of wire in such an instrument. The iron ends of the secondary generator would get very hot in consequence of the existence of the Foucault currents, and the core, if it were, as he imagined, solid, would also grow very hot. Coming to Harrison's system of 1878, the inventor described everything mentioned by plaintiff in his first claim except that he did not mention high tension and did not describe his secondary generator.

But there were plenty of efficient coils in the market ?—I do not think there were for this purpose.

Allowing for a high tension, you could have found suitable coils in the market ?—No doubt.

By simply following Harrison's description you could get a system of distribution with high tension in the secondary ?—With Ruhmkorff coils and appropriate wires he would be able to do it. But Harrison used iron where he should have used copper, which would increase the resistance and misdirect the lines of magnetic force.

Witness considered a tension which would be sufficient to kill a man a high tension.

Cross-examination continued by Mr. PIKE : The statement in Messrs. Gaulard and Gibbs's specification, that the quality and value of the current depended solely upon the construction of the induction coils, was not literally accurate, because it would depend also on the amount of current sent through the primary. That was clear enough. The word "resistance" was used in the specification not in its strict technical sense, but in a loose and vague sense.

Re-examined by Mr. ASTON : The statements contained in the provisional specification of Messrs. Gaulard and Gibbs were generally statements of electrical propositions.

Do these general statements affect the residue of the complete specification as it now stands amended ?—I think not.

Notwithstanding your attention having been called to several of these prior specifications, do you still adhere to your statement that prior to the 13th September, 1882, you do not find described the use in co-operation of the alternating dynamo sending alternating currents of high tension through long lines of wire upon which are placed at intervals secondary generators of the character described by the patentees ?—No, I do not find that in any one of them. If the secondary generators were constructed with solid iron cores they would not answer in Gaulard and Gibbs's instruments.

If they were constructed with solid iron cores, would there be any result such as is referred to in page 4 of the specification ?—No, there would be no reduction of the Foucault currents. There are little or no Foucault currents in the secondary generators described by Messrs. Gaulard and Gibbs.

In Messrs. Gaulard and Gibbs's generators, are there any conditions such as would generate any extraordinary heat in solid cores ?—No, there would be no such Foucault currents as would create any sensible heat. The avoidance of Foucault currents is necessary to the working of Messrs. Gaulard and Gibbs's patent, because if they existed they would make the inductive apparatus as hot in some cases as to be likely to destroy its insulation.

Digitized by Google

In any previous specification is there any reference to the desirability of avoiding Foucault currents in the secondary generators on the long main wire?—No instance occurs to me at this moment.

Witness, continuing, said that in the ordinary Ruhmkorff coil the primary wire was something like one-eighth of an inch, and the secondary about one-hundredth, possibly less. The length of the secondary wire would be measured by miles, and the length of the primary by inches, or at the outside by feet.

If you send a current of low tension through the primary, what would be the result as regards the tension in the secondary?—You would get a tension in the secondary amounting in many cases to thousands of volts.

Is it true that in all cases where the secondary generators are mentioned Messrs. Gaulard and Gibbs appeared to contemplate a lower tension at that point than there would be in the main circuit?—Yes. No doubt that is an advantage.

Do you know any other system, prior to 1882, where the secondary generators were worked in that way on the main circuit?—No.

Witness, continuing, said that Jablochkoff in his specification dated May 22, 1877, spoke of his invention as one for "dividing" the electric current. In those days the opinion was that it was a matter of great difficulty to get more than one light with one machine, and the great object of inventors was to divide the electric light and produce lesser lights with a smaller expenditure of power.

What was the result if a lamp broke down?

His LORDSHIP: Well, the same result as would happen if a candle went out (laughter).

Witness: Your lordship is correct. You would be in the dark (laughter).

Mr. ASTON: But in the case of a series of lamps what would happen?—If one went out all would go out.

Is there anything to indicate that the induction coil which works that lamp is to have a special character?—No. On the contrary, it is indicated in the specification that the tension of the secondary circuit must be very high in order to overcome the resistance of the lamp.

Is there anything in Jablochkoff's specification which would lead anyone to employ Gaulard and Gibbs's system?—No; I do not think there is. Jablochkoff's evident intention was to divide the electricity and produce a high tension suitable to the lamp he employed.

What do you say of Du Moncel's system?—He intended to have a high tension, which was precisely the converse of Messrs. Gaulard and Gibbs's plan.

His LORDSHIP: What is the objection to Du Moncel's?—It would not work incandescent lights. Jablochkoff proposed to use a solid core; but even with his arrangements a solid core would have resulted in very great waste and trouble.

If this induction apparatus were used in Gaulard and Gibbs's system would it work?—No; Bright's specification of 1878 was more like Jablochkoff's than Messrs. Gaulard and Gibbs's. Johnson's specification was a provisional description of "an improved induction apparatus."

Which would be more suitable, an ordinary Ruhmkorff coil, or the one described here?—An ordinary Ruhmkorff coil would be much better.

Do you think the induction apparatus described would be suitable for use on a long main wire such as is described by Messrs. Gaulard and Gibbs?—I do not think so.

His LORDSHIP: Could it be used?—It could be used; but it would be inefficient. That is, it would cause great trouble, and there would be great waste.

Mr. ASTON: Did you ever hear of any attempt to use it?—No, never.

His LORDSHIP: Is it not an invention in practical use?—I never heard of it. I never heard of Edwards and Normandy's apparatus being used. You would get sparking wherever you broke the circuit, which would be destructive of the apparatus. For long distances its use would be impossible.

Would Edwards and Normandy's specification teach you to make Gaulard and Gibbs's apparatus?—No.

His LORDSHIP: Is it near the mark, or a long way off?—It is tolerably near the mark, no doubt, but the suggested use of the intermittent current is misleading.

Mr. ASTON: In electrical inventions prior descriptions do sometimes go very near, do they not?—Very near.

Witness added that there was nothing in the specifications of either Deprez or Harrison that would lead one to construct Messrs. Goulard and Gibbs's apparatus.

This concluded the evidence of the witness, and the Court adjourned.

Tuesday, July 3rd.

At the sitting of the Court on Tuesday Mr. Aston called

Mr. JAMES SWINBURNE, electrical and mechanical engineer, electrician to Messrs. Crompton and Co., who first carried out the arrangements for lighting the Law Courts. He had for many years taken an interest in electrical matters, and in 1878 he saw the Jablochkoff system at work in Paris. At that time the subdivision of electricity was supposed to be a very great difficulty in the way of electric lighting. The difficulty was supposed to be in making a series of lamps burn independently from one machine, and arranging so that when one lamp went out it should not extinguish all the others. There were in those days a large number of applications for patents up to Christmas, 1882, when Messrs. Gaulard and Gibbs's system was brought to his notice. He had some conversation with Mr. Swan on the subject, and he saw the light exhibited at the Aquarium in 1883. He then investigated the construction of the coils, and he found that alternating currents were sent at high tension into the main circuit. Witness saw Messrs. Gaulard and Gibbs's specification in 1883, or early in 1884, and he did not find any difference between what was described there, and the information given him by Mr. Swan, and what he saw himself at the Aquarium. He ascertained that Messrs. Gaulard and Gibbs's apparatus contained an arrangement for causing the currents in the main wire to excite the induction coils in the local generators. The co-operating elements that he found in Messrs. Gaulard and Gibbs's apparatus were an alternating machine of high tension, secondary generators connected with the high-tension dynamo, the secondary coils giving a comparatively low tension. The primary coils were of high tension. Prior to the date of the patent, September 13th, 1882, witness did not know of these three elements co-operating together to produce the result of electric lighting in local insulations. Prior to Sept. 13 he did not know of electric lighting being successfully worked by means of an induction apparatus excited by currents in a state of high tension supplied by an alternating dynamo. The difficulty of distribution over large areas from a central station was unsolved prior to 1882, and was exciting great attention. He had seen Messrs. Gaulard and Gibbs's system in operation in connection with the Grosvenor Gallery, and enormously developed by licenses in America, where its employment was increasing very rapidly. Witness personally saw the application of it in four or five towns there. He had examined the induction coils, and in no case was there a solid iron core. The system would not work commercially with solid iron cores, and it would be an absurd thing to use them. It would not do to apply the Ruhmkorff coil to Messrs. Gaulard and Gibbs's system; it would not be their system if it were so applied. If any electrician were to do what was directed in Messrs. Gaulard and Gibbs's specification, using the secondary generators as described, he would be able to distribute electricity from an alternating dynamo supplying local installations. Witness had seen Messrs. Gaulard and Gibbs's secondary generators at work at the underground station at Charing Cross. With a slight difference in details it was the same apparatus as was described in Messrs. Gaulard and Gibbs's specification. He knew no other system of that kind in use now. If a high-tension current, say 2,000 volts, were introduced with secondary generators, there would be extreme danger where people were able to touch the wires or the fittings. Witness had heard Dr. Hopkinson's evidence as to the prior specifications, and had made himself acquainted with those specifications. He did not find described in any of them the three elements which distinguished Messrs. Gaulard and Gibbs's instrument. Du Moncel gave no description which would enable anyone to adopt Gaulard and Gibbs's system with the three co-operating elements. He entirely agreed with Dr. Hopkinson's evidence as to the specifications.

Cross-examined by Mr. MOULTON: Is there anything in Messrs. Gaulard and Gibbs's first claim which limits the current in the secondary generator?—He specially mentions high tension in the primary, and the inference is that it was not high in the secondary. You could not produce a light with high tension in the secondary circuit, and that would lead one to suppose that the secondary circuit must be low tension.

But you could use high tension?—Well, you could, but it is dangerous.

Is there anything to point to any particular class of secondary current which Messrs. Gaulard and Gibbs intended to introduce?—Only the points I have mentioned.

I will take that answer. Is there anything to limit the source of the alternating current?—No, not in the claim.

Is there anything to limit the class of the secondary generators?—Not in words.

I believe the claim consists of words?—It does. Taking the claim by itself, there is nothing. The specification spoke of an alternating-current dynamo. It was a common source of alternating current in 1882. The "special construction" of the secondary coils of the generators which Messrs. Gaulard and Gibbs spoke of referred to the fact that these coils were divided into six wires and mechanically connected. Messrs. Gaulard and Gibbs's secondary generators were arranged in series.

Is not the success of the distribution by secondary generators due to their arrangement in parallel?—That is not the only reason; it is only one of many reasons.

May I not take it that in America the generators are arranged in parallel?—Yes. Except in the experimental installation, witness did not know of any instance in which the generators were arranged other than in parallel.

With the exception of the passage which says you may vary the number of generators, there are no explanations or directions as to how you are to vary these dimensions and arrangements according to circumstances?—The patentees simply take an instance and give instructions. Continuing, witness said that Jablochkoff, as described by Du Moncel, had a high tension in his secondary generator. Witness did not think Jablochkoff distributed electricity; he simply divided it.

J. Johnson in his specification described the use of alternating currents derived from an alternating machine which are under certain circumstances to have a considerable quantity, as well as tension, and may be caused to travel all over a town, say five or six miles or more. Apart from the construction of the secondary generator, is not that an example of what is described in Messrs. Gaulard and Gibbs's specification?—I think that, apart from the construction of the generator, Johnson's idea was quite different.

But is it not what is described in plaintiff's specification?—I do not think it is. You cannot have a current of vast quantity going through Messrs. Gaulard and Gibbs's generators.

Do you say that in Messrs. Gaulard and Gibbs's secondary generators you cannot pass a current of considerable quantity?—No, not in the same sense that you can pass a current of considerable tension.

I put it to you that the generator employed by Johnson is superior to that described by Messrs. Gaulard and Gibbs because it has its poles united. Does not that increase its efficiency?—Yes, if there are no Foucault currents. Witness could not say if lamination for the purpose of overcoming Foucault currents was known in 1878.

Digitized by Google

Apart from the generation of the particular form of generator used, would not the description of Lake's system apply equally to the plaintiff's first claim?—I do not think it would; I see nothing about high-tension there. Witness did not think the description of Edward and Normandy's apparatus would supply a knowledge of Messrs. Gaulard and Gibbs's patent.

Re-examined by Mr. ASTON: The parallel arrangement of the lamps was an alternative plan to the series suggested by the patentees. If the wires were represented by a ladder and the lamps placed on the rungs that would be a parallel arrangement; if the rungs were removed and the lamps placed on the main supports that would be an arrangement in series. Messrs. Gaulard and Gibbs gave an arrangement by which the lamps could be worked in parallel. He thought electricians might have employed the parallel arrangement with the knowledge possessed at the date of the patent.

Throughout the whole of Messrs. Gaulard and Gibbs's specification did you find indicated the use of a dynamo other than one which would send a high tension current into the main circuit?—No, not in my opinion.

Taking the tension between the terminals of the secondary wire in the secondary generator and comparing that tension with the tension between the terminals of the dynamo machine, what would you find?—The tension between the terminals of the secondary wire would be very much lower. Witness, continuing, said that after having had his attention called to all the prior specifications, he was still of opinion that Messrs. Gaulard and Gibbs's patent was novel, and the commercial utility of it was enormous. The disadvantage of the arrangement of the lamps in series was that there would be difficulty in turning out the lamps unless they had the regulator mentioned in the patent. The directions contained in Johnson's specification would not lead anyone to adopt Messrs. Gaulard and Gibbs's apparatus. It would, on the contrary, lead to an absurd fallacy.

His LORDSHIP: What do you mean by an absurd fallacy?

Witness: He thought by putting his lamps on the secondary circuit he would not absorb any power from the dynamo. That touches the principle of perpetual motion.

His LORDSHIP: Do not let us go into that, pray (laughter).

Witness, continuing, said he thought Lake's specification would not lead anyone to construct Messrs. Gaulard and Gibbs's apparatus. He did not believe Lake's system provided for the distribution of electricity over a long wire for the purpose of feeding different installations, and he would say the same of Edwards and Normandy's plan.

His LORDSHIP said that it seemed to him the evidence was weak in establishing what Messrs. Gaulard and Gibbs really invented. So far it had gone to show what other people did or did not invent, and that they had not anticipated Messrs. Gaulard and Gibbs.

Prof. ADAMS, F.R.S., Professor of Natural Philosophy, King's College, London, stated he was on the jury which decided the merits of the exhibits at the Electrical Exhibition at the Crystal Palace, in 1882. At that exhibition there was nothing like the patent which formed the subject of that trial. The first instance he saw of electricity being distributed for lighting purposes from a central station by means of secondary generators was Messrs. Gaulard and Gibbs's system, when it was at work at the underground station of Edgware-road and Notting Hill-gate. It was produced by a high-tension dynamo machine, capable of producing a high-tension current, probably 2,000 volts. In the secondary generators the current could not have been more than 100 volts. He had never before seen such a system of distributing electrical power. He had read what were termed the prior specifications, and in none of them did he find anything which anticipated Messsrs. Gaulard and Gibbs's patent. The novelty in Messrs. Gaulard and Gibbs's invention was an alternating dynamo machine for the production of electricity. This current was carried by a system of distribution by means of fine wires over long distances with secondary generators, the primary wires of which received the current, and the secondary wires of which gave it out for use at local stations, where several lamps were to be lighted. The great object of electricians prior to 1882 was to sub-divide the electric light. The Ruhmkorff coil would not have been suitable for use in Messrs. Gaulard and Gibbs's patent. Witness had studied the construction of the secondary coils as shown in Messrs. Gaulard and Gibbs's specification. The effect of passing a current of high tenson over them was to produce a current of lower tension in the secondary circuit. The two forms of generators described in Messrs. Gaulard and Gibbs's specification could be used with a parallel arrangement of lamps. Witness agreed generally with what had been said by the previous witnesses as to the prior specifications.

Cross-examined by Mr. MOULTON: Is there in this patent one word which points to the possibility, or gives any direction for arranging these generators in parallel?—There were no directions.

And there is nothing in the figure which shows it?—No, it was not necessary.

But if you were to put generators, such as are described in Messrs. Gaulard and Gibbs's specification, on a high-tension current they would be both burnt up?—If you put one it would.

Witness said that in 1882 it was not novel to send a high-tension alternating current to a long distance for the purpose of being transformed into low tension.

If you wanted to do that, was it not the natural way to take the alternating current from an alternating-current machine?—Yes.

Then Gaulard and Gibbs simply used the most ordinary way of producing alternating currents?—I do not agree that it was the ordinary source of alternating currents at that time.

Re-examined by Mr. ASTON: You have stated that if one of these generators were placed in parallel it would be burnt up?—Yes; that would be owing to the small amount of resistance in the primary.

Was it not perfectly well known in 1882 that if too large an amount of electricity was passing through you could diminish it by increasing the resistance?—Yes.

Have you any doubt that any intelligent workman could have put the generators in parallel?—I have not.

Witness, continuing, said that in 1882 he had never heard of an alternating dynamo approaching anything like 2,000 volts; in fact, at the time of the exhibition at the Crystal Palace 800 volts was considered enormous, and the mention of 1,000 volts would make a person's hair stand on end. It was only since that year they had heard of the enormous pressure to which they were now accustomed.

Mr. JOHN H. GIBBS, one of the patentees, said he remembered being in Paris during the Electrical Exhibition of 1881. He then gave attention to electrical matters from a commercial point of view, and engaged the assistance of Mr. Gaulard as an electrical expert. Mr. Gaulard's mind had since broken down, and he was now in an asylum. His object was to convey electricity to a distance, and light glow lamps in various installations. He and Mr. Gaulard were working for nearly 18 months, and when they perfected their plans they obtained English, French and American letters patent for the invention. They exhibited it at Vienna, and it was afterwards employed at the Grosvenor Gallery. In 1883 a company was formed for supplying the apparatus, and five stations on the underground railway were lighted. The generator—an alternating current dynamo machine constructed by Siemens, was set up at Edgware-road. That installation cost them £4,500. It was a 15-mile circuit, and there were about 150 incandescent lamps and 4 or 5 arc lamps. He never knew and never heard of any such installation being set up before. In working the system they found that 85 to 95 per cent. of the power in the primary wire was reproduced in the secondary circuit, and there was not a single scientific man at that time who did not ridicule the system. The company to whom they sold their patent—the National Company—afterwards competed for a prize offered by the Italian Government for the best system of distributing electricity. After a demonstration at Turin—where he believed the circuit was fifty miles—the company received £400 and a gold medal. In 1884, they set up the installation at the Grosvenor Gallery.

His LORDSHIP: I do not see whither this evidence is tending.

Mr. ASTON: To show utility.

Mr. MOULTON: I am willing to admit that the distribution of electricity by secondary generators is a good thing.

Witness, continuing, said they had sent an installation to Tivoli, which was working satisfactorily. The generators were arranged.

His LORDSHIP: Is your company paying a dividend?

Witness: It paid one dividend.

Mr. ASTON: The existence of this petition does not tend to help you.

Witness, continuing, said that under the licence granted to the American Company the National Company was receiving "comfortable" royalties.

Cross-examined by Mr. MOULTON: In the early history of the patent witness wrote putting forward his views on the subject. At that time he believed his complete specification to be scientifically correct.

You know the scientific world did not agree with your view?—The scientific world did not believe in the possibility of doing what we professed to be able to do.

Do you mean to say scientific people did not believe that your patent involved perpetual motion and all sorts of absurdities?—Scientific men never said so to me. I believe the primary circuit at Tivoli is more than ten miles. It is worked on the "series" system. I believe there is another installation on that principle at work in the United States.

Did you ever say it was a *sine qua non* that there should be equal masses of metal in the primary and secondary circuits?—The masses of metal should be as nearly equal as possible to obtain a good return.

Is it true your secondary generator was based on this idea?—In one respect it was, because you cannot make an effective instrument without it.

Did either of your generators satisfy that requirement?—They came as near to it as the ordinary market size of the wire would admit.

Do you say that wire is not made of all sizes?—There are only certain trade sizes.

Will you say you chose these sizes because they were nearest to equal metallic masses?—It was one of the reasons.

Did you know there ought to be equal metallic masses in the two circuits?—Yes.

The Court then adjourned.

WEDNESDAY, JULY 4.

The first witness called on the Court resuming was

Prof. GEORGE FORBES, F.R.S., Consulting Electrical Engineer, who stated that he was well acquainted with Messrs. Gaulard and Gibbs's patent. The features which specially distinguished the apparatus were the selection of proper secondary generators, a high-tension main, and a proper alternating-current dynamo. Since 1883 he had seen many installations for electric lighting. Some of those covering short distances were on the direct-supply system; but for long distances he knew of none which were successful which did not employ the three elements combined in Messrs. Gaulard and Gibbs's patent. He had seen Messrs. Gaulard and Gibbs's system as described in the specification actually at work at the exhibition held at the Aquarium in 1883; the next time on a thoroughly practical scale, on the Underground Railway, in 1884; at the Grosvenor Gallery, and extensively in America. He was not certain as to the arrangement of the generators in the Grosvenor Gallery; but on the railway and at Pittsburg, in America, they were worked just as shown in the patentees' drawings. He had made himself familiar with the prior specifications, and in none of these did he find the three elements which he had described as distinguishing Messrs. Gaulard and Gibbs's apparatus. The secondary generators mentioned in Messrs. Gaulard and Gibbs's specification had divided cores. He knew now that such cores would make all the difference between success and failure. In some of the prior specifications there was a reference

Digitized by Google

to a divided core generally when the induction apparatus was used to give a high tension, but always with a "continuous current interrupted." In several of the specifications he found references to the use of a solid core. In every one of these cases the alternating current was employed. Prior to 1882 a good many experiments were known for determining the qualitative effects produced by different arrangements, but there was no measurement made as to the loss of energy produced by using particular kinds of cores in induction apparatus. With a solid core they would get, perhaps, 30 or 40 per cent. of the energy. They knew now that the loss of energy in a solid core was caused by the Foucault currents creating heat and using up the energy. He found it extremely difficult now to divest himself of the knowledge he had acquired since 1882, but he thought the qualitative effect of the Foucault current was known prior to 1882, but there was no quantitative experiment known to him until Messrs. Gaulard and Gibbs's system was invented. Other things being equal, an electrician in those days would obviously have taken a solid core, for the simple reason that it would make a better mechanical arrangement. Prior to 1882 he had never seen any experiment for ascertaining the effect of an alternating current upon a solid core as compared with a divided core. Prior to 1882, however, it was known that in the use of induction coils the tension of the secondary coil at the moment the primary coil was broken was enormously intensified by the use of the divided core. Witness believed at the time Messrs. Gaulard and Gibbs made their patent known the term secondary generator was new to the scientific electrical world. In all previous induction apparatus the object had been simply to transform or convert the tension from a low value to a high value without any great regard to economical results, but the object in Messrs. Gaulard and Gibbs's patent was to get a regeneration of the energy, and with that special object in view they designed their instrument and apparatus.

Cross-examined by Mr. MOULTON: In 1882, the importance of using a wire core instead of a solid one was thoroughly appreciated by the electrical world for the purpose for which it was then used.

Was the importance of economy appreciated?—No, economy was not.

But it was known that wire core ought to be used?—Yes, with a high tension in the secondary.

Are there any directions in this second specification of Messrs. Gaulard and Gibbs that the core should be made of wire?—It is distinctly stated so, with the object of preventing Foucault currents.

Mr. MOULTON: Do not try to mislead the Court.

Mr. ASTON: That is a most unfair observation.

Do you tell his lordship that that remark about the Foucault currents refers to the same cores which are spoken of as "the exciting cores which enable the gradations of the tension," and so on?—No; the core in the secondary apparatus is sub-divided in sheets.

I am talking of the "exciting cores." Are there any directions that those shall be made of wire?—Yes, on page 3.

That is the "exciting core," do you say?—Yes; those instructions were intended for both.

Where is there any direction that it is essential or important in the second instruction that the core should be of wire?—In his description of how to make a core he has said distinctly it shall be of wire.

Witness, continuing, said the arrangement of discs would work; but it was not the best arrangement.

Was it not known in 1882 that the tension in the secondary was in proportion to the number of turns in the primary?—No; probably at that time the problem had never been put to anybody.

Do you mean to say that has been discovered since 1882?—It has been announced since 1882.

And was never announced before?—Never; I am thoroughly of opinion it was absolutely unknown before 1882.

Taking your own description of the three co-operating elements in this patent, where do the patentees tell you how to select the proper secondary generator?—I do not think they ever make a great point of the particular parts; but they show two types which would work.

Is that the only answer you can give?—I do not care to go further than that.

Where do they speak of a high-tension main?—When they speak of sending a current 50 kilometres it is clearly understood that must be a high-tension current. They do not expressly refer to a high-tension main. The Pittsburg installation was put in this year after the commencement of the action.

Re-examined by Mr. ASTON: If an electrician endeavoured to carry out fairly the directions given in the specification he would be able to make secondary generators which would answer the purpose. There was nothing in the specifications to take him away from having generators with divided cores, the disadvantage of Foucault currents being pointed out. Any person wishing to use a solid core would do so, because it could be made in any shape, and included a greater quantity of iron than a sub-divided core, and because of the facility with which it could be bolted together. As regarded the quantitative results, he knew of no publication which said prior to 1882 that the tension in the secondary wires would be proportionate to the number of coils. The quantitative results would be known.

This concluded the case for the plaintiffs.

Sir HORACE DAVEY, for the defence, said that if the alleged invention had been true to the provisional specifications, and had made it possible to supply an unlimited number of lamps without any loss of energy in the primary current, it would undoubtedly have been of great value, but unfortunately, though that claim was clearly made for it, the achievement was not equal to the promise. There was a distinct difference between the original specification and the subsequent one, and he asked was the inventor at liberty to strike out what was said in the provisional specification to be the distinct feature of the claim, and to insert something different? The word "unlimited" of the provisional specifications meant that you might have as many induction coils as you pleased without impairing the value of the primary current, which was, therefore, constant; and if this had been true the result aimed at would have been achieved. The patentee claimed to have invented something which obviated all necessity for putting a limit upon the number of induction coils or secondary generators, which would be used with the primary coils, notwithstanding the fact that the current had been induced for the purpose of serving lamps at various points. But this being, unfortunately, untrue the whole system crumbled, and the word "indefinite" had been substituted for "unlimited" in the specifications, which was, of course, very different, and the claim for the special construction of generators had been also struck out. He should use the power to take the complete specification in its amended form as if it had been the original specification, and should also have regard to the disclaimed pattern for the purpose of keeping the patentee to the pattern as it had come down. The claim for the construction of secondary generators was abandoned, and the patentee admitted that they were already old. Then the claim for the process of distribution did not describe the invention as it was described in the original specification, but the claim was obviously vastly larger—"the employment of an alternating current of high tension for the generation on a number of secondary generators of induced currents individually utilised for the production of light or motive power." The claim had reference to generators of every construction, and thus went far beyond the supposed invention of the original specification. Having to deal with this claim as amended, he ventured to submit that by the confession of Dr. Hopkinson himself, of Swinburne, and Adams, there was not a shadow of novelty in the invention. If he had claimed a special kind of generator, or dynamo machine, or a special arrangement of the lamps, or special provision for their lighting it would have been different; but the claim was so wide that it brought within it every system in which an alternating current of high tension was used for the generation on induction coils of every description for the purposes of light and motion, and every such system would be an infringement of the patent. Could he maintain that position in the face of the evidence which had been given? In the third place, the wide difference between the claim as formulated at that bar and in the patent should be noticed. The system was hopelessly old in 1882 when this patent was granted.

Mr. JUSTICE KEKEWICH: My difficulty has been to see how the evidence and the patent agree.

Sir HORACE DAVEY: That is our difficulty also. They had produced half-a-dozen descriptions of alternating-current systems, and if he could see in public works descriptions of a system of alternating currents with or without high tension, with nothing about the tension, but with secondary generators, he was entitled to say that, on the ground of the invention being anticipated, the patent was not good. Dr. Hopkinson described the wire cores of the coils as the novelty, but he did not say that in the body of the specification. But if this was an essential, how was it that Dr. Hopkinson and Prof. Forbes did not point it out? How was it that the proper distinction between what was novel and old and between what was essential and not essential was not drawn? They were told that the great thing was the use of the wire coils, but they had the evidence of Dr. Hopkinson that the Ruhmkorff coil was before the date of this patent always made of wire, and that it was so arranged that you could use either the thicker wire as the primary and the thinner as the secondary, or *vice versâ*. There was no novelty in the divided coil; it was the most common form of induction coil, and no one in his senses would have used a solid core where the divided one was used according to the specifications. There was, too, an absence of all instruction that the divided core must be used; neither were directions given as to the number of the coils or convolutions for the coil or the secondary wire. They knew that the quality of the tension of their secondary wire would depend upon the cross section and the fineness of it, and secondly on the number of convolutions round the induction coil. The quantitative value, they were told, was not known before. But the patentee did not tell that, and it would be most material for regulating the tension. In regard to Fig. 3 on the specifications it was said that it was most important to overcome the difficulty of the Foucault currents by securing that the iron case in which the coil was contained should not be in contact with the coil itself. But it was the very use of that iron case which created the danger of the Foucault currents; they had nothing whatever to do with the coil itself. And the letterpress was alone in showing the splitting; the figure ignored it. Do away with the iron case, and the danger of the Foucault currents would vanish. The particular form of coil was not at all insisted upon as essential to the success of the process, and in the drawing of the second method of producing these currents, the core was shown as solid, with a handle such as used to be in vogue years ago for drawing it in and out. If this divided core was something which a workman would not use unless he had it pointed out to him, directions concerning it would, one would think, have been given. Sir Horace Davey proceeded to quote authorities bearing upon the necessity of a full description being given of all new patents, and asked his lordship whether if the use of a divided coil was essential to the success of this invention, the patentee had told them that it was so. Mr. Gibbs, in cross-examination, had told them it was a *sine qua non* that the mass of metal in the primary and secondary circuits should be equal, and that he knew this at the time the patent was obtained. Then he ought to have said so; but he told them nothing of the kind in the first specification. He had not told them either how many convolutions there should be round the coils. If these points were essential, what was there to inform the world that that was so? This was an obligation from which an inventor could not escape—to explain the features of his invention as they were beneficial to the public to the best of his knowledge at the time. The learned counsel proceeded to support this position by quotations. The claim, he

Digitized by Google

continued, was one for an alternating current, from whatever source and from any kind of energy, to produce light from lamps of every description It might be asked how was it, if this plan was so well known in 1878, that no trace of its general use was found until 1882. Well, it was not true that it was not used, for Jablochkoff's system was in full vigour in Paris. But the real reason of its remaining in abeyance was that the incandescent light was not known except as a scientific curiosity. The system arose out of simple elements which were in everybody's hands, but there was no lamp fitted for the light, and therefore the system was not used. The almost universal method of using this system was by parallel and not by series. Dr. Hopkinson was uncertain whether they contemplated that or not, and the directions given were not sufficient to enable that method to be applied to the invention. In order to fit an induction coil for use in parallel, alterations in the whole were required which were not pointed out in the pattern, and therefore if the pattern was intended to explain the use in parallel as well as in series he had not given the directions which would be required to enable it to be used in that way. As to whether the specifications as originally prepared described the same invention as the amended specifications, the duty of the patentee was to describe the end of his invention in the provisional specification, and the final must not go beyond or be distinctly different from or larger than was the original. He wished to lay special stress upon the word "ascertain" in the rule that the inventor must "ascertain" how his invention is to be carried out, and what is essential and what is not. This had not been done in this instance. Sir Horace proceeded to refer to Du Moncel's description of Jablochkoff's system as he saw it worked, and to show that in its main features it was like the system now under discussion. Dr. Hopkinson's criticism upon this was that high tension was not used, and that his secondary generator cores might have been solid. But there was no ground for this statement, as it was not recorded whether high or low tension was employed. The tension was adapted to requirements, as admitted by Mr. Swinburne and Mr. Adams. There was in reality no definition of high tension, except that it meant that you regulated the tension so that it should be sufficient for your purposes. Messrs. Gaulard and Gibbs were, in fact, merely teaching a man the best way of using an old machine, and he quoted precedents to show that in such a case a patent should not be granted. Dr. Hopkinson admitted that the process described by Du Moncel was precisely the same thing as Messrs. Gaubard and Gibbs's system, except that that did not mention the tension. He said it was used to supply a high-tension lamp. Why because in that particular instance it was used to supply a high-tension lamp he should say the process was confined to high tension surpassed his (Sir Horace Davey's) comprehension. It was said that in this system the primary current was of a low tension compared with the tension in the secondary current. But when it was the common knowledge and property of mankind that you could increase the tension that objection speedily vanished. In regard to the system of Edwards and Normandy, Dr. Hopkinson said they did not use an alternating machine ; but he admitted that alternating dynamos were well known before the date of this invention in 1878 A dynamo machine was nominally an alternating machine, and you made it into a continuous one by the use of the commutator. There was not one iota of difference between this discovery and that except that the earlier one was perhaps more clearly and accurately described. Here you simply put on a commutator to make the alternating current of the dynamo continuous, and then by another machine you made the current alternating again. What Dr. Hopkinson had said on this point was an illustration of the straits to which the best men were sometimes put to support a thesis. The protection sought was against the use of any alternating current produced in any way, so that if any one were idiotic enough to adopt Dr. Hopkinson's suggestion, and put on his reverser, he would still get an alternating current which would be within the respondent's patent, and an infringement of it. The system of Deprez was that of an ordinary current of high tension to be used for the purpose of inducing currents for use at distant stations. The only criticism made upon this by Dr. Hopkinson was a practical admission of the case as regarded that authority. Bright's theory was that it was necessary to adapt the size of both his primary and secondary wires to his requirements. The general system of lighting by means of induced currents was perfectly well known, and therefore the new points of Gaulard and Gibbs's system must be confined to the particular description of apparatus employed. In regard to Johnson's system, Dr. Hopkinson did not think his secondary generator would work very well. That Johnson's was not a perfect form did not take away from it the quality of being an anticipation of a patent which claimed the whole process. In the case of De Meritens' system the iron case was a difficulty, but not so great as it was in that of Gaulard and Gibbs, and the coils might be arranged for either tension or quantity. Curiously this system anticipated Messrs. Gaulard and Gibbs even in their errors, for it was announced that there would be no loss of energy in the primary wire. If it was said that De Meritens' generator was not perfect, it might be replied that neither was Gaulard and Gibbs's, and that if the system failed on that account in the one case, it did in the other. If you broke off the ends of De Meritens' coils you would have the same form of generator as Gaulard and Gibbs's. Dr. Hopkinson believed Lake used the solid core, but there was nothing whatever in Lake to show whether the core should be solid or divided, and if figures were to be relied upon those attached to Messrs. Gaulard and Gibbs's specification would be inconvenient to them. When it was known that Ruhmkorff's coils were used for induction purposes, it would be perfectly unwarrantable to say that he confined himself to the use of the undivided core.

On the conclusion of Sir Horace Davey's address the Court adjourned.

Yesterday (Thursday) Sir William Thomson was examined on the part of the defendants. The report will be continued in our next issue.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *June 23rd*, 1888.

The agitation against overhead wires in this city seems at last to have reached a definite point, where action succeeds discussion, and where the strong arm of the police is used to enforce the provisions of the law. In my last letter I made reference to the steps that are being taken to remove the dead wires from the streets. The more the matter is investigated the more remarkable becomes the number of such dead wires strung around the city, on well nigh every street, at well nigh ever possible or impossible angle. One of the early estimates as to the extent of such wires placed the quantity at not less than 10,000 miles, but a second detailed examination is promising to bring the total up to twice as much. Of course all these wires cannot be taken down at once, but where owners can be found for them the work has already begun; and in the case of wires that belong to nobody, the Board of Public Works has been called upon to render its assistance. In one case, General Newton, who is the Commissioner of Public Works, has been requested to remove a big cable running pretty well half the length of business Broadway. It was put up by the Baltimore and Ohio Company, but was found unsatisfactory, it is said, and was rejected. Then the company passed into the hands of the Western Union Company, which declined to saddle itself either with the dispute or with the cable. Thus it happens that the cable might go on hanging until some time in the next century, but for the decision of the Subway Board to have it removed, with its other less conspicuous companions. Of course, when all the wires are removed, as well as the abandoned poles, our streets will present a less ragged appearance than they do now. The Subway Board has also given notice of its intention to condemn every electric light station that has not been examined and properly passed by July 1st, and to see by July 15th that all conductors shall have been placed in conduits where such provision has been made. In order to perform this work with discretion, the Subway Board has also just selected, as its electrical expert, Mr. Schuyler S. Wheeler, of whom there is the highest opinion entertained in technical circles for electrical and engineering ability. Mr. Wheeler is already at work, and there is every indication that before the summer is over a most decided advance will have been made in regard to putting the wires under ground in New York.

A great deal of public attention has been directed during the last week to the performance of the electric launch "Magnet," the first boat of its kind, I believe, to make its *début* in New York waters. This boat was built early this year on the designs of Messrs. Anthony and Frederick Reckenzaum. She is 28ft. long, 6ft. beam, 3ft. deep amidships, and draws 2½ft. of water by the stern. She is equipped with a Reckenzaum motor, weighing 420lb., driving a two-bladed screw 18in. in diameter. She carries 56 cells of the battery made by the Electrical Accumulator Company, weighing about 2,400lb. All told, the machinery weighs about 3,000lb. A speed of 12 miles an hour can be attained, but it is at the expense of the total mileage. The accumulators are arranged along the bottom of the boat, snugly under cover. Above them runs a bench nearly the whole length of the boat, giving seating accommodation for nearly 20 passengers back to back. The accumulators are arranged to work in a straight series of 56, or in two parallel groups of 28 cells each. They are capped at the top with rubber to prevent slopping in a rough sea, and stand in a bed of sawdust. For some time past this boat has been in use as a pleasure craft on the Passaic River, getting its charge at the Electrical Accumulator Factory on the river bank, at Newark. At the present time another launch, much larger, is being built at one of the yards up the Hudson River, also to be run by storage, the Electrical Accumulator Company supplying the batteries. I hear that the peculiarity of this boat will be the disposition of the batteries, which are to line the sides of the ship, leaving room in the middle for a cosy cabin. This boat

Digitized by Google

is said to be nearly ready, so that before long New Yorkers will become familiar with the spectacle of boats driven by their own ballast.

Matters phonographic occupy a great deal of public interest just now. It will be remembered that Mr. Edison's phonograph was exhibited at the Electric Club here a few weeks ago. I hear it whispered, however, that the machine, before it is put on the market for commercial purposes, will undergo a number of modifications and improvements. In the meantime, it is reported from Washington that the Tainter graphophone has been brought to such a degree of perfection that it is more than equal to the phonograph, besides being a less complicated piece of mechanism. How far this claim can be substantiated I do not know, but those who have had conversations with the instrument speak of it very enthusiastically. A company with $1,000,000 capital has just been formed in this city, under the laws of New Jersey, to sell the machine, and I suppose that pretty soon several of them will be in use. So far as can be learned, there is not much difference between the phonograph and the graphophone, as both employ the method of cutting the record into or upon wax, Mr. Edison using a tube wholly of wax, and Mr. Tainter a paper tube with a prepared waxen surface The latter gentleman, I believe, claims broadly this method of re-producing speech from a record thus cut, as distinguished from the method of punching or indenting, as practised with the phonograph when it was first brought out.

On Tuesday last, before the American Institute of Electrical Engineers, meeting by special invitation at Columbia College, Mr. F. J. Sprague read a very interesting and able paper on "The Solution of the Municipal Rapid Transit Problem." Mr. Sprague's solution was, of course, an electrical one, and he took occasion to point out the many advantageous ways in which electric motors might be employed to expedite passenger travel in such a city as New York. As to horses, he pointed out the many objections, and added the notable fact that with them the operating expenses are about 82½ per cent. of the gross receipts. With the cable system he showed also that the operating expenses were high, for the reason that only about 20 per cent. of the power of the engines was actually availed of in moving the cars. Coming to electricity, he showed that the percentage of power recovered for actual use was higher than that in other such systems; that it was not open to the objections brought against steam, with its many inconveniences; and that a car with electrical equipment occupied about 35 per cent. less space in the streets than the horse car, which means a great deal in crowded thoroughfares. As to the potential of the current to be used, he did not favour anything above 400 volts, which he considered perfectly safe for all practical purposes, and not in any way likely to endanger a human being, though perhaps a horse or mule might not find it agree with its constitution. In substantiating the many arguments which he presented, Mr. Sprague made specific reference to his big road at Richmond, Virginia, which is now in such successful operation. This road was illustrated by means of about sixty or seventy stereopticon illustrations, prepared specially for the occasion, and giving a most vivid idea of the many difficulties which have been encountered and triumphantly overcome. This road is now running about thirty cars, and carries about 60,000 passengers a week, the number being rapidly on the increase. It is believed that before the year is out the number of cars will be at least doubled, if, indeed, the whole street car service of the city is not made electric. Mr. Sprague made an application of the results obtained at Richmond to the conditions now to be dealt with in New York, and pointed out how the emergency might be met in various ways, such as a four-track underground road from the Battery Park up town, with two branches in residential and suburban districts. This line would be supplied with power and light from four central stations, which would be able to make enough money from the sale of power by stationary motors to pay the whole running expenses of the railway itself. The Paper was intensely interesting, and when taken up for discussion in the fall, will, without doubt, bring out a great variety of additional opinions and data.

We are awaiting the nomination of the Republican candidate for the Presidency by the Convention now sitting at Chicago. The telegraph service of the whole country is in a state of the greatest activity, and the wires are kept hot with messages from morning till night. Some notion of the amount of matter to be handled may be formed from the statement that there are now over 500 special correspondents at Chicago, each of whom is sending out his news by telegraph. The telegraph companies and press associations have, as usual, made very extensive preparations, but the competition this time is by no means as great as it has been before.

ELECTRIC LIGHT AT THE COPENHAGEN EXHIBITION.

(FROM OUR OWN CORRESPONDENT.)

The Grand International and Scandinavian Exhibition at Copenhagen was opened on the appointed day, May 18th, by the King of Denmark. The bulk of the exhibitors—at least those from the three Scandinavian kingdoms, Denmark, Norway and Sweden—had their exhibits in readiness, and the buildings had already been completed a considerable time beforehand. Some of the other countries were more or less behind their time, but with exception of the German section the whole is now finished. This Exhibition is a very large affair, the grounds covering about 60 acres, and the buildings are both large and numerous. The main hall is a remarkably fine structure, but unfortunately the electric light has not been extended to this building, which is closed for the public before dark. There is, however, no lack of electric light, and several firms have very interesting installations. One of the more important is that of the Swedish firm, Palmerantz and Co., Stockholm. Outside the main entrance they have an arc lamp of 2,000 candle-power, and eleven more are to be found in the grounds, most of them lighting the promenade along the main building. Another interesting installation is that of the Allgemeine Elektricitäts Gesellschaft, Berlin, whose arc lamps are very effectively fixed in lampettes in old German style. This firm supplies the electric light for the Horticultural Pavilions, the grounds to the east of the machinery hall, and the bridge between these and the main grounds. To the right of the promenade is a pavilion, very prettily lighted by incandescent lamps, from S. Schuckert, Nürnberg, exhibited by his representative for Denmark, Mr. L. Lund. The chandeliers are from the firm of Spinn and Sohn (Limited), Berlin, by their agent for Denmark, Mr. F. Berg. Not far from there is a number of arc lamps from the well-known Danish firm of Prof. C. P. Jürgensen, which has lately been transformed into a limited company; the same firm has also supplied the lighting of the Aquarium by incandescent lamps. Another pavilion is lighted by incandescent lamps, both single and arranged in chandeliers, from Palmerantz and Co., Stockholm. Prof. Jürgensen's establishment has also supplied the incandescent lamps to the Duval restaurant and to the quaint edifice in the shape of a bottle erected by the large Tuborz Brewery. S. E. Hanberg's Engineering and Electrical Company, or as it is now termed, Koefoed and Hanberg (Limited), is represented by the incandescent lamps in the restaurant close to the machinery hall; the lamps are quite artistically arranged in a chandelier and lampettes of glass from the firm of J. Fritzsche, Copenhagen. The exhibitions of the Asuig and Novz are lighted from installations by the Submarine Mining Corps, part of the Machinery Hall by arc lamps from Siemens and Halske, Berlin (representatives for Denmark, Otzen and Phorstenson, Copenhagen), and the grounds at the various agricultural buildings by arc lamps from L. Lund, Copenhagen. The firms enumerated here are also exhibiting dynamos. We shall in a future article have occasion to return to this subject and the various exhibits, among which are one or two novelties of considerable interest.

CORRESPONDENCE.

MAXWELL'S THEORY OF ELECTRICITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It is perhaps hardly worth mentioning, but the diagram in Mr. von Tunzelmann's paper on page 233, labelled "Maxwell's Representation of a Magnetic Field," is not copied from any paper of Maxwell's, but from one of mine.

It is, of course, a merely accidental slip; and Maxwell's theory has undoubtedly been the foundation of all I have attempted, but the removal of Maxwell's "idle wheels," or connecting particles supposed to constitute electricity, and the introduction of the two kinds of electricity as physical

Digitized by Google

entities, seems to me to make all the difference between an artificial analogy and a possible semblance of the truth.—Yours, &c., OLIVER J. LODGE.

University College, Liverpool, June 30.

SHACKLE OIL INSULATORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: With reference to your remark in last week's issue that the oil shackle insulator which I stated that I had designed had been anticipated by Messrs. Johnson and Phillips, the inventors and patentees of oil insulators, I think you must be misinformed, because I left my sketch of the oil shackle insulator with Messrs. Johnson and Phillips themselves for a quotation in February last, and I am quite positive that no question of that form having been anticipated arose at that time, and it was considered that the small space between the rim and the oil cup was likely to present some difficulty in manufacture. This, however, was not the case, the insulators having been delivered perfect in form and very well made, with an important improvement introduced by Mr. Pell, by which the strain of the wire is always thrown on the centre of the bolt, thus preventing the fractures which sometimes occur in shackle insulators from the warping of the material in the baking.

The sketch which I sent you was made from the original, and did not contain Mr. Pell's addition.—Yours, &c.,

F. HIGGINS.

The Exchange Telegraph Company (Limited),
17 and 18, Cornhill, E.C., July 3, 1888.

[In the Note in our last issue to which our correspondent refers we said that the shackles were "already" made by Messrs. Johnson and Phillips, and our correspondent has perhaps not unnaturally taken this expression to imply that the firm in question had anticipated his design. We should have said that the shackles are "now" made by Messrs. Johnson and Phillips. We are sorry for the ambiguity, which this explanation will doubtless remove.—ED. *E.*]

THE CONDITIONS OF REGULATION IN DYNAMOS FOR CONSTANT POTENTIAL.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I was much interested by Mr. Esson's article on the "Conditions of Regulation in Dynamos for Constant Potential," and the discrepancy between the actual excitement of the series-winding to produce self-regulation and that indicated from the magnetisation curve of the machine is a point which has caught the attention of everyone practically engaged in dynamo building. There is no doubt that even the amended formula given by Dr. Thompson will not serve for the winding of machines of every kind, and is on that account insufficient; but I think that the discrepancy noted by Mr. Esson is very much exaggerated in the instances he has chosen on account of the meagre proportions of his field-magnets.

The necessity for extra excitement on the series coils springs from the presence of self-induction in the main circuit occasioned by the reversals of current in the coils of the armature. This vicious phenomenon may be greatly checked by pushing the magnetisation of the core to a very high degree. The resistance or reluctance of that portion of the magnetic circuit which is under the influence of the excitement proceeding from the current reversals in the armature is then so great as to ensure a practically sparkless collection on the commutator together with a corresponding diminution in the amount of "waste excitement" of the field.

From the same cause the necessity of giving a "lead" to the brushes will disappear with the increased field section, and although *per se* the fact of giving the brushes "lead" does not entail an extra excitement of the field, it is symptomatic of the disease to which such a requirement is attributable.

As a matter of fact, it appears from the figures given by Mr. Esson that the induction in his armature core is only 8630 per square centimetre, or 9·35 lines per square inch, in Kapp's notation. This is very low indeed, and follows from the insufficient section of the magnets. The ratio of the sections of the armature and field cores is as 1 : 1·41, and to obtain a really good induction in the former it should be at least as 1 : 2.

For a considerable time I failed myself to realise the tremendous magnetic leakage which is inherent in ordinary continuous-current dynamos, and, in consequence, I always designed the fields too small. Latterly, however, by correcting this error, I managed to practically eliminate all the ill effects of self-induction from the machine, and I have very little doubt that if Mr. Esson tries the same remedy he will be more mercifully disposed towards Dr. Thompson's formula.—Yours, &c., GUY C. FRICKER.

12, Delahay-street, Westminster.

UNIPOLAR INDUCTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: On referring to the statement under heading 3 of my third article (page 203) I find that Mr. N. G. Thompson's difficulty arises from an omission which had escaped my notice, and I must thank him for calling attention to it. The statement should read "as the *positive and negative* lines of force cross the two portions of the circuit in the same direction, there is neither increase nor decrease in the total number passing through the circuit." The error consists in the omission of the words in italics. The same thing would be expressed by saying that each line of force crosses the circuit twice in opposite directions. It would perhaps have been better, to prevent misunderstanding, to have spoken throughout only of the positive direction of the lines of force, and instead of stating in the third paragraph of the same column that "for every positive line of force, coming from the north pole of the magnet, which crosses the circuit in a given direction, a negative line of force coming from the south pole of the magnet will cross it in the same direction," to have simply said that every line of force will cross the circuit twice in opposite directions, namely, as it enters it and leaves it respectively.

As Mr. Thompson misquotes the expression, "passing through the circuit," replacing it by the phrase, "cutting the circuit," I think he must have failed to see that what is meant is an increase or decrease in the number of lines of force passing through the area enclosed within the circuit, which is usually expressed more briefly by the phrase, "passing through the circuit." The statement that this increase or decrease is zero is absolutely equivalent to the statement that every line of force cuts the circuit twice in opposite directions, as is pointed out in the second paragraph of the second column of the article referred to.

Mr. Thompson's statement that there will be no current when the terminals of the fixed circuit are symmetrically situated with regard to the poles is correct in the case of a uniformly magnetised bar. The statement that this is equivalent to the terminals being at equal distances from the poles is ambiguous. I presume that what Mr. Thompson means is that the distances of one terminal from the two poles are respectively equal to the distances of the other terminal from the two poles, which would be perfectly true.

The general statement applicable to any magnet producing a field symmetrical about its axis would be that there will be no current when the terminals of the fixed circuit are situated at any two points on the surface of revolution traced out by any one line of force.—Yours, &c,

G. W. DE TUNZELMANN.

LEGAL INTELLIGENCE.

Swaby v. Watt and Others.

In the Chancery Division of the High Court of Justice, on Friday last, the action of Lewis Swaby against Hugh Watt and others, directors of the Maxim-Weston Electric Company (Limited), came on again before Mr. Justice Stirling. It was a motion on behalf of the plaintiff to restrain the defendants from forfeiting or cancelling 400 shares which the plaintiff held in the Maxim-Weston Electric Company, to prevent

Digitized by Google

the defendant Howell from acting as director of the company, and the defendants from excluding the plaintiff from Board meetings, and to allow him to act as a director. The company was registered in 1881, the capital being £172,000. The plaintiff had allotted to him 2,000 shares, in addition to 400 fully paid-up shares, and in 1883 he was elected a director. In 1887 the defendant, Mr. Watt, was elected chairman and managing director of the company, at a salary of £1,200 a year, the three directors being the plaintiff, Mr. Brown, and Mr. Watt. By the Articles of Association it was enacted that two directors should form a quorum. In March, 1886, the plaintiff and Mr. Brown attended a directors' meeting, and the latter verbally intimated that he intended resigning, but gave no written intimation of his intention, as required by the Articles of Association, and it was said there was no acceptance of his resignation by the Board. An entry, however, was made in the minute book to the effect that Mr. Brown's resignation had been accepted by the Board. Mr. Watt subsequently informed the plaintiff that he intended to appoint Mr. Howell, M.P., a director in the place of Mr. Brown, provided the plaintiff accepted the proposal. The plaintiff wrote in reply that his approval of that appointment depended on the Board's decision. Another entry subsequently appeared in the minute book that the plaintiff accepted Mr. Howell's appointment, and that he had been appointed a director at a meeting. But it turned out afterwards that the only person present at the so-called meeting was the chairman, and that by his direction Mr. Howell, after having returned thanks for his appointment, took his seat as a director. The plaintiff remonstrated at the course which had been pursued, and he subsequently received a letter from the defendant's solicitor to the effect that as he had not paid up the money due on his 2,000 shares, the 400 shares he held would be cancelled, and as he had ceased to be a shareholder he could not act as a director. The fact, however, was that these 2,000 shares had, about twelve months previously to the receipt of that letter, been transferred to Mr. Watt and duly registered in his name in the books of the company, and as regarded the 400 shares nothing was due upon them. The defence was substantially that Mr. Howell had been properly appointed.

Mr. Pearson, Q.C., appeared for the plaintiff; Mr. Hastings, Q.C, and Mr. A. Young for the defendants, Watt and Howell; Mr. Buckley, Q.C., and Mr. Robert Wallace for the company.

His LORDSHIP, in giving judgment, said the case disclosed some peculiar transactions. And the ground upon which the defendants had cancelled the 400 shares was the most curious one he had ever heard of. As to the appointment of Mr. Howell in place of Mr. Brown, he came to the conclusion that Mr. Brown's resignation had not been accepted by the Board, and that Mr. Howell had not been duly appointed. As regarded Mr. Watt, he had acted in a high-handed manner towards the plaintiff. There was no ground whatever for cancelling the 400 shares which the plaintiff held, and he was accordingly entitled to act as a director. The plaintiff was therefore entitled to the relief he claimed.—Judgment for the plaintiff accordingly.

COMPANIES' MEETINGS & REPORTS.

United Telephone Company (Limited).

The eighth annual ordinary general meeting of the shareholders of this Company was held at the City Terminus Hotel, Cannon-street, on the 3rd inst., Mr. James Brand presiding.

The SECRETARY (Mr. Thomas Blaikie) read the notice convening the meeting. The report and accounts were taken as read.

The CHAIRMAN said: Gentlemen, you have all received a copy of the report, and I have no doubt studied the accounts. I will not trouble you with going over these accounts just now, as I know that there is a gentleman, a friend of mine, in the room who is going to make some inquiries about the accounts by-and-bye, and then I will endeavour, by myself or by some of my friends here, to answer him as well as I possibly can. Very likely you will have noticed that at the commencement of the present session our Board, being desirous of giving effect to the recommendations of the Select Committee of 1885, lodged a Bill in Parliament asking for this Company the powers which the Committee said we ought to have, and giving a central authority the powers of inspection and control suggested by that Committee. Well, the Postmaster-General was not disposed to aid us in passing this Bill. He suggested that the Local Government Board, perhaps next year, might be the proper persons to deal with it. We did not desire to have any conflict with the Government or the authorities, and, therefore, we withdrew the Bill for the present. We may have something more to say about this matter next year. Then, I should say a word or two on a very important subject indeed, and that is as to our relations with our subsidiary companies (cheers). This is a point on which I think there should be no misunderstanding, and bringing it before you prominently to-day was suggested to me by some remarks I read yesterday in the *Financial News*, which is a paper that is very cleverly written, and which evidently takes very great interest in all telephone companies generally, and in the United Telephone Company in particular. I was much surprised to read in the report of the meeting of the South of England Telephone Company, held on the 29th of June, some remarks reported to have been made by the Chairman of that company as to the relations of his company with the United Company. In reply to Mr. Billet, the Chairman said this: Mr. Billet asked, "Has there not been some suggestion for these outlying lines to be connected with London?" And the Chairman is reported to have said, "We are not an independent company so far as that is concerned—one-half will have to be run in the United Company's district. We have urged this matter on them repeatedly, but we get no further. With regard to Brighton, it is a joint line between the United Company and ourselves. Under the old arrangement we pay one-half, and derive no immediate advantage from it. It was an experimental line." Well, now, I feel sure that Mr. Bateson, the Chairman of the South of England Company, would not willingly say anything but that which he believed to be true, and I can only suppose that he has forgotten the numerous interviews that we have had with him, and the proposals that we—the United Company—have made from time to time. Let me tell you the fact as it stands. The United Company have, through the General Post Office, run a wire to Tilbury, among other places, at their own expense. On the 20th of April, 1887, we wrote to the South of England Company, offering to work this line at our own expense and give the South of England Company half of any profit that was made, and to bear the whole loss, if any, ourselves; and I pledged myself to Mr. Bateson that if at the end of one year this manner of working this trunk line proved unsatisfactory to him or his company, the whole matter should be revised and settled in a way that should be satisfactory to his company. Now, again, as to the Brighton wire, I may tell you about that. The General Post Office ran this wire also for the United Telephone Company. For two years, 1884 and 1885, we paid £446. 10s. per annum ourselves for rent to the Post Office. After that I arranged with the Chairman of the South of England Company that his company should pay one half of the rent of the Brighton wire for 1886 and for all time after; but that the United Company would at their own cost fit up the necessary apparatus in the switch room at Brighton. Since then the South of England Company have worked the Brighton trunk wire without let or hindrance from the United Company. The United Company have paid the rent of the wire for 1887 and 1888 to the General Post Office; but we have not yet received any payment on account of these two years from the South of England Company. On the 29th June the South of England Company wrote agreeing in a great measure to certain proposals I had made in the letter I have mentioned of the 20th April, 1887, and yet at the meeting that was held on Friday last—that is the same day as that on which the letter was written—the Chairman of the South of England Company is reported to have said, in reply to Mr. Billet's question (who said: "Surely it could be no intention of the United to stifle its own children?"), "We have proposed terms and cannot get them"—that is, the United Company—"to second them at all. They refuse to enter on the subject at all. Since I have been in the chair I have constantly urged this matter on the United Company, but have got no further to-day." Now, such statements as these, of course, are calculated to do great injury to the United Telephone Company in the eyes of you gentlemen, the shareholders, and of the public in general; and I think it my duty, therefore, to contradict them, and to dwell at some length on this subject. A good deal of the property of the United Company, as you know, consists in its shares in the subsidiary companies, and we should be fools indeed if we tried to stifle our own children. It is not true that the United Company puts obstacles in the way of trunk wires. It is our own interest to push trunk wires with all our might. We are doing it now, and it will be one of our chief operations in the future. The National Company is as anxious in this direction as we are to join its different centres on to our system. On the 3rd January this year the United and the National Companies made arrangements mutually satisfactory for the erection and working of a trunk wire to Birmingham. I think I may say that the difficulties of the way-leaves are practically overcome. We have been met in a liberal spirit by the landowners, with whose property we interfere, and we hope that within a month we may be able to commence the construction of the line. This line will provide nearly half the distance required to connect Manchester and Liverpool with London, and also enable Nottingham, Leicester, Derby, Sheffield, and other midland towns to speak to London, as also the northern towns of Newcastle and Sunderland. The same desire for inter-communication exists between the Western Counties Company and ourselves, and friendly negotiations are in progress for connecting London and Bristol, and the Western Counties have got as far as Bath. They have considered it best, however, before tackling with us the heavy outlay for the trunk wire to London, to connect their head-quarters at Bristol with Newport, Cardiff, Swansea, &c., and the coal and iron fields of South Wales. You are aware that our agreements with our subsidiary companies prevent us from running truck lines from London to any town beyond twelve miles and working without the consent of the subsidiary companies. They all know, however, that we are willing to join hands with them. I think I have said enough on this matter to show you how groundless are the curious statements that are constantly being made—(A Shareholder: No, certainly not. The Chairman: I will speak to you by-and-bye, sir. Laughter)—that are constantly being made as to the dog-in-the-manger policy of the United Company. It is hardly

Digitized by Google

possible for the shareholders to realise the difficulties that we meet with and have to overcome, and I wish the shareholders would lend us their aid to a greater extent than they do. It is surprising how few of the shareholders are subscribers to our lines. I do not think that 10 per cent. of our shareholders subscribe to our exchanges. However, we do the best we can, and during this year we have increased our mileage of wire from 7,500 to about 8,700 miles. There are at present free call rooms for the use of subscribers existing at Oxford-court, Chancery-lane, the Law Courts, the House of Commons, Regent-street, and Edgware-road, and arrangements have been made, in deference to the wishes expressed by some of the shareholders, and as a matter of experiment, for establishing paying call rooms at Kilburn, Balham, Limehouse, Earl's Court, Denmark-hill, Holloway, Brixton, Greenwich, Notting Hill, Clapham, Croydon, Richmond, Stratford, Putney, Wandsworth, Norwood, and Brentford. I must tell you that these paying call rooms have not been so much pushed by the United Telephone Company as, perhaps, by some of the other companies further north and west. Our opinion is that these call rooms in London, as a matter of revenue, will not be very successful. In the north they have proved a good source of revenue, but then that is because of the trunk lines existing between town and town, and the public who are not subscribers take advantage of the call rooms to communicate from town to town, and are willing to pay 3d. or 6d. or 1s., or whatever it is, I do not know exactly how much. As far as I know, the call rooms established in the towns have not been made much use of for what we call local communication. However, we think it is a good thing to try the experiment, and if it does not pay us directly by revenue we think it will pay us by educating people more and more to the inestimable blessings of the telephone. Well, then, we have put up during the year new iron derricks, at great expense, of course, to replace those derricks that were destroyed in what the *Financial News* calls "the good old snowstorm" (laughter). We have got one at Oxford-court, another at Queen Victoria-street, Mincing-lane, East India-avenue, Cornhill, the Hop Exchange, and Smithfield, and there is another in preparation for Heddon-street. We have opened a new exchange at Smithfield with a largely-increased capacity, and the lines have been transferred from the old exchange to the new. With the view of centralising the work of switching, three minor exchanges have been closed—those are Leadenhall-street, Stratford, and Shadwell. The exchanges having been transferred to the larger exchange, a new multiple switch-board has been erected in the new exchange at Smithfield, and preparations are well advanced for erecting multiple switch-boards at East India-avenue, Westminster, and Chancery-lane. We have opened and got in very good order now a new trunk line to Croydon on our own poles, free from the induction of railway poles and other electrical wires, and it is working very well. It has only been opened about a month, and we hope it will be a source of good profit to us. Then I come to a question that has no doubt occupied your minds a good deal, and that is the question of amalgamation. Various reports have got abroad respecting the proposed amalgamation of this company with its affiliated companies, and it is desirable, I think, now that we are all together, that I should explain to you shortly in what position that matter actually stands. All sides are agreed that an amalgamation would certainly be desirable in the interest of all the companies, provided it can be settled in a manner fair, not only in view of the present state of each company, but also taking into account to some extent their future prospects. This latter consideration will involve questions of considerable difficulty, and it will be necessary to ascertain how far the accounts of the several companies have been made up on the same basis as regards allowances for depreciation of wires, plant, &c., and also as regards the allocation of expenditure between revenue and capital. To enable us to have a basis for discussion on these points, the accounts of the various companies are now in the hands of Mr. Griffiths, an eminent accountant; and when his report comes in—and it will certainly take some weeks to prepare—we shall be able to meet the directors of the other companies and see how far their views accord with ours as to the proportions to be allowed to the several companies. Of course, before making any arrangements for amalgamation it would be necessary to obtain the consent of the Postmaster-General to the various licenses being transferred to the new company. Subject to this being obtained, I am personally very much impressed with the advantages of carrying out this scheme, and my colleagues on the Board heartily concur in my views. If all sides are animated with a desire to settle the questions that may arise in a fair and liberal spirit, I can see no reason why the thing should not go through (cheers). It would be idle, however, to shut our eyes to the fact that questions may arise on which different opinions may legitimately be held, and, of course, they may be more or less difficult to solve. The question as to the value to be attached to undeveloped business is an apt illustration of what I mean. Such questions I hope we shall always meet in an equitable spirit; but, of course, we have your interests to protect just as much as the directors of the other companies have the interests of their shareholders to look after. I know very well that this matter should be settled promptly, for until it is settled it retards the development of the Company's business in new lines and connections in the direction of which I have already spoken. You will have seen from the accounts laid before you that during last year we expended nearly £29,000 on this account, but this has been solely within the metropolitan area. The development of the system of trunks will, of course, involve a large expenditure of capital, and one considerably larger than we can provide, as we have hitherto done, out of the sums debited to revenue for depreciation and other things. If and when it is necessary to raise money for this purpose we will, of course, call you together and ask your advice on the subject. Well, then, as to law, during the year, Mr. Winterbotham has sent me this report, which I will read to your. He says: "Since the decision of the Court of Appeal in favour of the Edison patent in the action against Messrs. Bassano and Slater, of Derby, there has been no serious attack upon the Company's patents, and the Directors were in hopes that the many ingenious attempts to get outside the patents were at an end. However, at the beginning of the present year Mr. Campbell Swinton, a Scotch gentleman, brought out an instrument and formed a small company to manufacture and sell it, and as the company was beginning to do business on a somewhat extensive scale it became necessary to take action. The directors are glad to say that an interim injunction was promptly obtained, which has for the present put an end to further sales, but the defendants appear inclined to fight the whole question over again. As the question of the validity of the company's patents has already been decided by the Court of Appeal, and the directors have the best possible advice (that of the present Attorney-General and other well-known counsel) that the instruments are infringements, they are in no way anxious about the result. At the same time it is much to be regretted that the law allows limited companies without any uncalled capital to put a patentee to all this expense after the question has already been litigated and decided." Well, now, I think I have said enough for the present. But before I move the first resolution, that the report and accounts be taken as read, I shall be glad if any gentlemen have any questions that they ask them now. After a pause he added: I was waiting to see if any questions were going to be asked about the accounts, but in order to have this brought about I have to move—

"*That the report and accounts be taken as read, be received and adopted, and that a dividend for the half year ended the 30th April last of 10s. per fully-paid share and of 5s. on the new shares, less income-tax, be paid, making a total dividend for the year of 15 per cent. on the paid-up capita of the company.*"

The DEPUTY-CHAIRMAN (Mr. J. S. Forbes) seconded the motion.

Mr. SICHEL referred to the expenses which had been involved by the great snowstorm, and said it had been double the amount which the chairman stated at the last meeting. The public was, he said, dissatisfied with the service of the telephone, sufficient facilities not being given for its use, and that was shown by the small increase in the receipts. He advocated an increase in the number of call offices, coupled with a system of issuing tickets to the public for five guineas per annum, entitling the holders to go to any office in the metropolitan area, and to use it as and when they liked. He had seen that system at work in Paris. He was satisfied that the business of the Company was capable of immense development, and measures should be taken with that end, especially in view of the termination of their patents.

The CHAIRMAN then replied to certain questions on the accounts which had been put by Mr. Begg.

Mr. BEGG afterwards contended at some length that the management of the Company was both extravagant and inefficient, and in regard to the latter view maintained that there ought to be an all-the-year-round, including Sunday, service given by the Company. The Chairman had said he was willing to join hands with the sub-companies about the trunk scheme; but willing to join hands was not the attitude of the Board of a telephone company. The Board should insist, and if others would not go ahead in the matter, compel them to. They could not get a communication of any sort except in Tilbury and Brighton. He would impress on the Board the absolute necessity of something being done in the matter at once. The great bulwark of the Company was its patents, which were three years within their expiration, and unless they made good use of the remaining time they would not get from the Government, which, no doubt, must ultimately buy the property, anything like what they ought to get. He did not wish to propose anything hostile, but to test the feeling of the meeting he would move that the accounts be not passed, and that a committee be appointed to investigate the affairs of the Company, and report to the shareholders.

Sir JULIAN GOLDSMID, Bart., M.P., strongly complained of the Directors' fees, which he regarded as excessive. He seconded the amendment.

Sir E. H. GALSWORTHY dissented from the view which had been taken by the last speaker.

Other gentlemen having addressed the meeting.

The CHAIRMAN, in reply, said he had not given a guarantee that the expenses connected with the snowstorm should not exceed £15,000.

Mr. FORBES, in further reply, regretted that Sir Julian Goldsmid had left the meeting, as the hon. baronet had been the parent of what one might treat as the personal question. He was sorry that a gentleman in the position of Sir Julian should have hazarded imputations, and he was still more surprised to find that a lawyer and a gentlemen and a man of the world should get up what, after all, was a trumpery question of the remuneration of the Directors. He hoped that the shareholders would listen (oh, oh). He was also a bit of a lawyer himself, and he thought he knew as much about this special class of business as Sir Julian. He (the speaker) would venture to say that in the Articles of Association of almost every foreign company of importance the most common thing was a contract—a legal and a moral contract between the man who lent his money and the man who, in addition, lent his brains and his knowledge to his partners. That was the nature of almost every bargain of every *société anonyme* in France, Germany, and other countries; and it was not limited to those countries, but was very common in this country, too. He wanted to know what principle could be more judicious, and he had been very glad to find that the gentleman who spoke first (Mr. Sichel) enunciated the principle when he said that he thought the best way of governing the Company was not by the Directors, with whom the shareholders had made a bargain, but by engaging the services of some competent man whom they should remunerate with a fixed sum and a commission. That was exactly the contract which the shareholders had made with the Directors. Under that arrangement the Board received £1,500 a-year, and he would undertake to say that in one or two instances in

Digitized by Google

the history of the Company a single hour's work would have justified the Chairman and himself in taking a good many £1,500's; and the shareholders would find that out in the future. He wanted to ask any reasonable man, first, whether the principle on which Directors were paid was unreasonable? Why were they taking such large fees? First of all, because they had "gone into the swim" with the shareholders and held a very large number of the shares; and, therefore, in that respect the Directors had done their share with the shareholders; and then the Directors also found the brains and the knowledge, and had the burden of responsibility of working the shareholders' money, to the latter's advantage. Having done so, they received £1,500 up to the point when the shareholders received a 10 per cent. dividend. But what was the good of talking about one year? The average was the thing to talk of in this business. For the five years during the labour, anxiety, discouragement, and difficulty of making the Company—because the Directors had made it—they received about £210 a year on the average. Who among the shareholders, having the capacity and the knowledge to do the work—as no doubt many of them had—was going to do the work for £210 a year? By means of the Directors' money and that of the shareholders, and with the use of the brains and knowledge of the gentlemen forming the Board, the dividend had been got up to beyond 10 per cent., and the Directors were to receive 20 per cent. of all the money they made for the shareholders over 10 per cent. Was it unreasonable for the shareholders to receive 80 per cent. for every 20 per cent. paid to the Directors of the amount beyond the sum required to pay a dividend of 10 per cent.? He would defend before all the world the bargain that had been made. The Directors accepted the position, the responsibility, and the labour of the business in that bargain, which he maintained was a reasonable bargain, and one which had redounded enormously to the interests of the shareholders of the Company, whose investment had now paid them for some years over 10 per cent., the Directors having also put by a substantial reserve fund. The shareholders having received more than 10 per cent., and since, therefore, the legal and moral claim of the Directors to be paid a commission on the profits had come into force, what had the Directors received over the three years? £750 each. Was that an undue remuneration under the circumstances he had mentioned? If the shareholders thought so, let them find other men who would do what the Directors had done for them in the past, and who were as capable of doing what they would have to do for the Company in the future. It was all very well to talk about amalgamating, but there were not five men in the room who had the least idea of the danger before them. They had three years of the patents. After that the whole world might be their competitors, including the Post Office. Were the shareholders going to discourage the Directors by blinding their eyes to what the Board had so far done for them? Whatever their criticisms might be on the manner in which the Company's business had been conducted they had made a substantial property of it—with the £5 share worth £15, a 15 per cent. dividend, and a reserve fund of about £120,000. That was not such a very bad outcrop of a Company which had been only eight years in existence. He had made those statements, so that Sir Julian Goldsmid and their critics might think about them. It was a pity that critics did not think or know before they complained. Mr. Begg was evidently a man of great ability; but that gentleman had enlarged very much upon the manner in which the Company had neglected its business by not developing, among other things, call offices. He was sure that if Mr. Begg had had before him the knowledge and the figures possessed by himself, that gentleman would not have been so very surprised in connection with this question of call offices. The exchange business was the cream of the United Company's business, and the call office business was a mere bagatelle. He saw by the report of the Lancashire and Cheshire Company for last year that their gross income was £81,000, and their trunk wire and call department yielded them £6,500. The gross income of the National Company was £90,000, and their fees for messages were £1,800. The United Company had 8,700 miles of wire, 4,835 exchange subscribers, and 21 exchanges, through which the whole of this enormous number of calls had to be forced. They were to endanger a service not yet nearly as efficient as it ought to be, and might be made, by letting Tom, Dick, and Harry go to call offices and use the wires that were already flooded by the messages of the ordinary subscribers. That was the position of the matter, and who was going to run the risk? If Mr. Begg had any greater responsibility at his back than he had at that moment, of talking about it, he would not run the risk; and the Directors were not going to. The position of the National Company was quite different. That Company had 10,900 miles of wire and 7,926 exchange subscribers, but they had 214 exchanges spread in all the great towns and in all the districts over the area which they covered. The United Company had, speaking in round figures, more than half the number of the subscribers which the National Company had, but they had to force all their work through twenty-one exchanges, and exchanges the complications and difficulties of which were not equalled in any city of the world or any place. If he had a private wire with a telephone at one end and his own servant at the other he could generally get attended to. If he was at the Westminster exchange and wanted to call to a gentleman in the City he had to go through one, two, three, or four exchanges before his message caught the gentleman he wanted to talk to. They knew pretty well what was being done in America and in Edinburgh and other cities; but he said they must compare like things with like, and there was no comparison with any place or city in the world and London. Let them look at the mere question of way-leaves; everything they did was on sufferance. Therefore, their exchanges were multiplied because they could not get the shortest cuts, and for that reason their service is made inefficient. He felt sure that Mr. Begg was not going to press for a committee of inquiry into their business. At all events, he was not going to submit to such an inquiry. Either the Directors knew their business, and were worthy of the shareholders' confidence, or they were not, and in the latter case the shareholders should turn the present Board out and put in Mr. Begg. He knew of no form of censure so unjust or so insidious as the appointment of a committee. They had seriously considered the "fad" of Sir Julian Goldsmid about the enormous payments to the Directors; but he (the speaker) was not going to work for £200 a year, for he could carry his brains to a much better market. The Directors knew the defect of this system and its difficulties; the shareholders knew its defects but not its difficulties. That was the difference, and anyone who was put in the place of the Board would soon find them out. Nothing but long service could give the Directors the knowledge of which the present Board were possessed. He trusted that the gentlemen who had put questions were satisfied with the replies, and he hoped that the shareholders would reflect that in view of the position of the Company and the difficulties as to the proposed fusion with the other companies, and the question of competition at the end of three years, as well as the delicate questions which would then arise, it was no favour to the Directors to have paid them the fees which the shareholders, under a binding contract, had agreed to pay them.

Mr. SICHEL remarked that what he had had in view had been referred to by Mr. Forbes in the last part of his speech, his contention being that they ought to get all that they possibly could out of the concern before the end of the three years which the Company yet had.

The CHAIRMAN put the amendment in the usual way, and announced that two had voted in favour of it, and that it was lost. He then put the original motion and declared it carried unanimously.

The retiring directors and auditors having been re-elected.

Sir E. H. GALSWORTHY then proposed, and Mr. BEGG seconded, a vote of thanks to the Chairman and Directors, and the motion was unanimously agreed to.

The CHAIRMAN acknowledged the vote, and the proceedings then terminated.

South of England Telephone Company (Limited).

The annual general meeting of this Company was held on Friday, the 29th June, at Winchester House, Old Broad-street, under the presidency of Mr. D. Owen Bateson.

The SECRETARY (Mr. Fred. L. Robinson) having read the notice convening the meeting,

The CHAIRMAN said: We are pleased again to meet you, gentlemen, and to give an account of our proceedings during the past year. The report and figures which we have sent you show our progress. We cannot pretend that our district is one that is capable of any sensational development; still, I think we may lay claim to endeavouring to make the best of what has fallen to the lot of our Company. You will note that our exchange lines have increased from 1,130 in 1887 to 1,521 in 1888, and private lines from 348 in 1887 to 386 in 1888. In this latter item the new lines have been many more than are indicated by these figures, but they have been counterbalanced by an unusual number of withdrawals. I apprehend this is occasioned by some of our subscribers having been induced by apparent cheapness to try some of the new-fangled instruments which are so industriously advertised nowadays. I do not think there will be a continuance of these withdrawals, as there is no doubt but that our instruments are the best; indeed, we have already had some subscribers who, after trying the new ones, have discarded them and returned to us, assuring us that the old are the most reliable, and are decidedly superior.

As regards our gross rentals, they stand at £19,325, against £15,190 in 1887, showing an increase of £4,135, and after deducting the amount carried forward to this year, £6,970. 16s., for unexpired terms, and the royalties paid the parent company and the Post Office, £2,501. 16s. 10d., we show a gross profit of £9,852.

As the business increases the management and working expenses must naturally increase. This year we have expended on these accounts £5,099, against £4,198, showing an increase of £901, which, considering the additional extent of business done, is not an undue sum. In the accounts last year there was a debit of £1,365 odd carried to revenue on account of the damage done by the snowstorm of December, 1886; happily this year we have met with no such disaster, and we trust for similar immunity in the future. We have taken every pains to guard against it, and some of our extra expenditure is due to charges for strengthening our system where we have found it necessary.

As regards our capital, it will be seen that all the 20,000 Six per Cent. Preference shares are now issued. The 3,567 remaining according to our last report have been all disposed of at par, viz., £2 each, completing the entire issue with this sum paid. It will be needful ere long to call another 10s. Your Directors, however, will delay it as long as possible, knowing that the 6 per cent. interest will be an additional charge on the resources of the Company. It will be noted that we have spent £16,457 on capital account this year, against £16,077 last. You must be aware that in a new company such as ours, almost the entire of our expenditure is in construction work, and comparatively little on maintenance. The charge for running trunk lines comes very heavy on us, and hence a great part of this large sum. This year we have completed the Brighton, Shoreham and Worthing lines, as also Brighton and Lewes. We are now engaged between Lewes and Eastbourne, as well as between Canterbury and Dover. These two lines we hope to complete within a month from this time. Our next trunk lines will be between Canterbury and Ramsgate, Deal and Ashford. For these lines we are busy canvassing for way-leaves. These are generally accorded us without much difficulty by both landowners and road authorities, and I beg to tender our thanks for their consideration in this regard. Now and then undue difficulties have been placed in our way, which we get over as best we can, and we have

Digitized by Google

occasionally been obliged to vary our routes, often to our material cost. One line between Margate and Westgate we have been obliged to abandon altogether, consequent on the obstructive policy of the representatives of a charitable institution, much to our annoyance and the great inconvenience of our subscribers. I am happy to think that this is quite an exceptional case, and an example not likely to be followed elsewhere.

Our various exchanges are doing fairly well; Brighton especially runs far ahead of all the others, thanks in some measure to the efforts of our energetic and capable manager there. Our subscribers, exchange and private, have increased from 284 in 1887 to 397 in 1888, and we have no fear that they will stop at this figure. The trunk lines between Brighton and Worthing, and also to Lewes and Eastbourne, will doubtless much assist the development of this exchange. Our more business centres are not so active. However, Reading, Northampton, Norwich, and Ipswich progress fairly. We have lately made a diligent canvass of all these towns and their environs, which we think will increase the number of our subscribers eventually. Cambridge continues to do well, and at last Oxford seems to be awakening to the advantages of our system. We have taken great pains to bring ourselves prominently before the authorities and tradespeople in this town. We are now engaged in developing new exchanges in Tunbridge Wells and Tonbridge; Guildford will also follow in due course. It would appear as though this would be a paying business if we are not hampered by way-have difficulties. The exchange in Canterbury promises well. We are making this a centre from which various lines are to radiate, namely, to Dover and Folkestone in the first place, and this portion of the scheme is nearly complete. Subsequently lines to Ramsgate and Margate will be run, also Deal, Sandwich, Ashford and probably Faversham. If we carry out this plan each place on the radius will be able to speak to our subscribers at the other towns on the radius. We think the scheme will tend much to develop our system in this district, and be a great convenience to our supporters. Westgate will necessarily be excluded from partaking of the advantages of the scheme, for the reasons I have before stated. I may say, however, that we are quite prepared to reconsider our determination of abandonment if the circumstances are so far altered as will enable us to run our lines.

Our instruments continue to give every satisfaction to our subscribers, and we have very few complaints of bad service. These few are almost invariably occasioned by accidental contacts of the wires, and are set right with as little delay as possible. In many of our districts we have established fee call offices worked by automatic call boxes, by means of which anyone, subscriber or not, on payment of 3d. for local, or 6d. for trunk communication, can call up subscribers on the exchange and have three minutes' conversation. Up to the present we have not derived much revenue from this source, but we shall continue it, as we can see what an immense convenience it is to our subscribers and others, and it tends to bring our system before the public and to popularise it. We expect when it becomes better known what the advantages of this scheme are, that we shall derive some profit from our outlay, which has been considerable.

Now, as regards a dividend, it will be seen from the net revenue account that we have had £4,964. 1s. 2d. to dispose of. Out of this we have already paid £1,849. 0s. 6d. in two half-yearly dividends on the Preference shares, leaving us with £3,115. 0s. 8d. Our auditors have strongly advised us to commence a reserve, so we have decided to place £500 to such a fund. I must say that I hardly see the force of the auditors' argument as to this, it appearing to my mind somewhat of a farce endeavouring to secure a capital of £340,000 by anything we can possibly lay aside out of our limited income. It has, however, this good feature, that in case of any disaster, such as a snowstorm, we shall have something to fall back upon without jeopardising our dividend. I am not disposed to accumulate this fund beyond the need in this direction, but this is for your consideration in the future. With the balance, £2,615. 1s. 8d., we propose to pay a dividend of ½ per cent., amounting to £1,500 in the aggregate, carrying forward £1,115. 0s. 8d., which is much the same as last year, viz., £1,058. 9s. I do not know that I have anything more to say, and I will move

"*That the report and accounts for the year ended April 30, 1888, now presented, be read and adopted.*"

Mr. ALEXANDER MACGREGOR seconded the motion.

Mr. BILLETT observed that it used always to be said that their lines would come into London.

The CHAIRMAN: You must remember, so far as that matter is concerned, that we are not an independent company. Half of these lines have to be run in the United Company's district. We have repeatedly urged the matter on their notice, but we get no further.

A SHAREHOLDER inquired the position of the Brighton line.

The CHAIRMAN: It is a joint line between the United Company and ourselves. We pay for half the expense of it; but we really derive no immediate benefit from it except that it develops our Brighton exchange. Anyone on our Brighton exchange can use that line, but they pay nothing for it. In further reply, the Chairman admitted that it would not pay to make a trunk line to other places on the same terms; but it was an experiment.

Mr. STEWART: Is there not some arrangement in prospect for the consolidation of all the telephones on the system?

The CHAIRMAN: Something has been mooted with respect to that, and there has been a meeting of the different subsidiary companies and the United Company. A sub-committee has been formed to investigate on what terms it can be done. It has gone no further than that.

Mr. BILLETT asked whether it was not part of the agreement that the Company would have power to construct other lines to London.

The CHAIRMAN: No, the point of the agreement was this—that we can run our lines to the 12-mile radius; but we cannot do any work in the United Company's district, and until they consent to it we are perfectly powerless. In further reply to Mr. Billett, he repeated that they had brought the matter several times before the notice of the United Company.

A SHAREHOLDER: Is there not a line being made northwards? I see it on the map.

The CHAIRMAN: It is merely on the map at present, I believe.

Mr. BILLETT: There can be no intention of the United Company to strangle its own children. This is a child of the United Company, and surely they should give us every facility.

The CHAIRMAN: Surely they ought, but certainly they do not.

A SHAREHOLDER: Have they proposed any terms?

The CHAIRMAN: We have proposed terms, but we cannot get them to second it, or to suggest any alternative terms.

A SHAREHOLDER stated that it was thoroughly understood by the late Chairman of the Company that they would be able to come into London when they had a sufficient number of subscribers.

The CHAIRMAN: I really do not know what arrangement they made with the late Chairman, Mr. Kendal, but I do know that since I have been in the chair I have constantly urged this matter upon the United Company's attention, and I am no further in regard to it to-day than I was three years ago.

Mr. BILLETT: Perhaps that explains the reason why with five million people they have only four thousand subscribers. I think they should be requested to give us every facility.

The CHAIRMAN: Well, I hope you will attend the meeting of the United Company, and bring this matter up there. My representations have had no effect at all.

A SHAREHOLDER inquired whether any steps had been taken to get a quotation for the shares on the Stock Exchange?

The CHAIRMAN: We have moved in that matter, and it has been laid before a leading stockbroker, who has also represented it to the Stock Exchange. The Stock Exchange would require a great many alterations in our Articles of Association before we could get a quotation, though the changes would be merely formal. We should have to hold a special meeting of the Company before we could make these alterations. We contemplate doing it, and we shall not be very long before we do it, if we find it necessary. It rests with you, however. If you want a quotation we will do our best to get it.

Mr. STEWART: The Chairman suggests that any shareholders here who are shareholders of the United Company should attend the meeting of that Company. They are very large shareholders in this Company, and it is in their own interest that they should do all they can to further the extension of this Company's business.

The CHAIRMAN: I say "Hear, hear," to that decidedly.—He then put the motion in the usual way, and having declared it carried unanimously, said: The next resolution is one that you will probably agree to—

"*That a dividend at the rate of ½ per cent., free of income-tax, on the ordinary shares, be declared payable on the 3rd July.*"

Mr. MACGREGOR seconded the resolution, which was carried unanimously.

On the motion of Mr. MARSHALL, seconded by Mr. BILLETT, a resolution was passed to the effect that £200 should be paid to the Directors for their services during the 12 months ended April 30, 1838.

The CHAIRMAN then proposed the re-election of Mr. Thomas Fielden Campbell. Those who best know Mr. Campbell most appreciate his value, and until he was laid aside by illness a short time ago, he was one of our most regular attendants. I think you will be standing very much in your own light if you do not re-elect him.

Mr. MACGREGOR seconded the motion, expressing his regret that illness prevented Mr. Campbell from being at the meeting that day.

The CHAIRMAN put the resolution, and it was carried unanimously.

On the motion of Mr. BEVIS, seconded by Mr. CHATER, Mr. J. Weise (of the firm of Turquand, Youngs and Co.) was re-elected auditor for the present year with a remuneration of 40 guineas.

A vote of thanks to the Chairman and Directors was then passed.

The Chairman having acknowledged the compliment, the proceedings terminated.

United River Plate Telephone Company.

Report of the Directors to be presented to the shareholders at the second ordinary general meeting, to be held at Winchester House, 50, Old Broad-street, E.C., on Thursday, the 12th inst., at three o'clock:—

The balance-sheet and profit and loss account of the Company's operations during the sixteen months ended 31st March last, after paying all working expenses abroad, debenture interest and London charges, and after writing off the whole of the preliminary expenses in London and Buenos Ayres connected with the formation of the Company, amounting to £4,139. 6s. 8d., shows a profit of £34,942. 1s. 6d., from which has to be deducted the sum of £10,775. 19s. for loss on exchange, leaving a net profit of £24,166. 2s. 6d., out of which an interim dividend of 2½ per cent., or £6,250, was paid in October last, the actual available balance being thereby reduced to £17,916. 2s. 6d.

Out of this balance the Directors recommend that a further dividend of 4½ per cent., being 4s. 6d. per share, free of income tax, be now paid, which absorbs £11,250; that £5,000 be placed to a depreciation and renewal fund; and that the balance of £1,666. 2s. 6d. be carried forward to the credit of profit and loss account for the current year.

The shareholders will observe that the capital expenditure during the sixteen months amounted to £56,415. 3s. 7d., which includes the cost of the business in Rosario, and the establishment of the exchange at La Plata, of which the Directors informed the shareholders in their circular of 3rd October last, and also the purchase of an exchange at Corrientes,

Digitized by Google

while the expenditure at Buenos Ayres is represented by the important and costly erection of the multiple switch-board, and the improvements of the general system there. In order to further develop the Company's business, the Directors have recently made a provisional agreement for the purchase of a rival exchange business at Rosario, the possession of which, in conjunction with the business previously obtained, will, they believe, constitute a valuable addition to the Company's property, as those who know the increasing importance of Rosario will readily appreciate.

The rapid extension of the Company has made it necessary for the Directors to be in a position to further consolidate and render thoroughly efficient the various points of the Company's system, and so ensure larger working results. With that view the Directors now propose, acting under the powers conferred on them by the Articles of Association, to increase the capital of the Company by £25,000, being the equivalent of 5,000 fully-paid shares of £5 each, which shares they will offer at par to the shareholders now on the register *pro rata*. These shares will rank for dividend as from the 1st April last, and, with the warrants for the dividend now recommended, a circular and form of application will be forwarded to each shareholder.

Notwithstanding considerable difficulties during the period under review, many of which were inseparable from the inauguration of an amalgamated business, the Directors have every reason to be satisfied with the progress made, and believe that the business of the Company will now steadily develop and increase.

Under the Articles of Association Mr. J. Irving Courtenay, Deputy Chairman of the Company, and Mr. R. E. Bateman retire by rotation at this meeting. Mr. Courtenay, being eligible, offers himself for re-election; Mr. Bateman, owing to pressure of other engagements, does not seek re-election, and the Directors propose the appointment to the vacancy thus occasioned of Mr. John Coghlan, who since January last has given the Board the benefit of his advice and of his experience in the River Plate, and whose appointment the Directors therefore recommend the shareholders to confirm as from that date.

The auditors, Messrs. Cooper Bros. and Co., also retire, but offer themselves for re-election.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended June 29th, 1888, were £3,941.

CUBA SUBMARINE TELEGRAPH COMPANY.—The number of messages passing over the lines of this company during the month of June was 4,114, estimated to produce £3,000, against 3,613 messages, producing £2,929 in the corresponding month of last year. The traffic receipts for the month of March, estimated at £3,800, realised £3,835.

DIRECT SPANISH TELEGRAPH COMPANY.—The traffic receipts of this company for the month of June amounted to £1,690, against £1,561 in the corresponding period of last year.

EASTERN TELEGRAPH COMPANY.—The traffic receipts of this company for the month of June, 1888, amounted to £48,096, and to £45,426 in the corresponding period of 1887.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY.—The traffic receipts of this company for the month of June, 1888, amounted to £41,764, and to £35,138 in the corresponding period of 1887. Increase, £6,626.

NEWFOUNDLAND LAND COMPANY.—The report of the committee of the shareholders of this Company (the shares of which are principally held by the shareholders of the Anglo-American Telegraph Co.) has recently been issued. The committee are of opinion that the 64,000 acres of land allotted to the company should be partly sold or leased in small lots for farming purposes, and partly for fish-curing warehouse sites. They advise the appointment of a competent engineer to survey the company's land, with a view to ascertaining its mineral wealth. Finally, they propose the raising of the necessary funds by the issue of debentures not exceeding £10,000, to be issued at 25 per cent. discount, and carrying interest at the rate of 7½ per cent. per annum.

TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY.—The directors of this company have decided to pay an interim dividend of 12s. per share on the 17th inst.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended June 29th, 1888, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company, were £3,278.

WEST COAST OF AMERICA TELEGRAPH COMPANY.—The traffic receipts of this company for the month ended June 30th, 1888, amounted to £5,225.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half month ended June 30, were £2,553, as compared with £3,052 in the corresponding period of last year. The March receipts, estimated at £7,036, realised £7,051.

NEW COMPANIES REGISTERED.

BUCKINGHAM ELECTRIC LIGHT AND POWER SUPPLY COMPANY (LIMITED).—This company was registered on the 22nd June, with a capital of £5,000, in £1 shares, to carry on, in the town and county of Buckingham, the business of an electric light and power supply company in all branches. The subscribers are:—

	Shares.
A. C. Rogers, Prebend House, Buckingham, miller, &c.	1
J. Wilson Thorpe, Buckingham, merchant	1
G. Watson French, Buckingham, ironmonger	1
Albert Fyle, Buckingham, draper	1
Henry Thorpe, Buckingham, coal merchant	1
L. Varney, Buckingham, photographer	1
W. Habgood, Hazlebrook, Buccleuch-road, West Dulwich, electrical engineer	1

The number of directors is not to be less than three nor more than five; qualification 25 shares.

ELECTRICAL PURIFICATION COMPANY (LIMITED).—On the 23rd June this company was registered, with a capital of £15,000, in £1 shares, to acquire and work the letters patent No. 1,333, dated January 27th, 1887; No. 15,760, November 17th, 1887; No. 15,939, November 19th, 1887; No. 472, January 11th, 1888; No. 1,105, January 24th, 1888, granted to William Webster, relating to the electrical treatment of sewage and other impure liquids. The subscribers are:—

	Shares.
*Wm. Webster, 50, Lee-park, electrician	2,000
*Thos. Slater, 19, Great George-street, engineer	100
J. Crow, 54, Wickham-road, Brockley, secretary	1
J. Hunter Jones, C.E., Cairo, Egypt	1
*V. Cassavetti, 6, Clarendon-place, Hyde Park	1,000
W. Porter, Baring-lodge, High-road, Lee, engineer	1
*Edwin Webster, 9, Lee-terrace	1,500

The number of directors is not to be less than 3, nor more than 4; the subscribers denoted by an asterisk are the first.

Offices—**WINCHESTER HOUSE, OLD BROAD STREET, LONDON, E.C.**

The principal objects of the Corporation are :—

1. Performing the duties of Trustee, Executor and Administrator.
2. The Insurance of Bonds, Shares and all other Securities lodged with the Corporation against risks of all kinds.
3. The Issue of Warrants and Certificates against Securities deposited, and making and procuring advances on such Warrants.

The Office of Trustee or Executor is to private persons usually a thankless post, involving much anxiety, time and money, and frequently leads to serious actual loss; whilst death, illness and change of residence necessitate frequent fresh appointments, and consequent expense to the parties interested. The Corporation undertakes all the duties of Executor, Trustee or Administrator for reasonable remuneration proportioned to the work and responsibility in each case.

The Corporation insures existing Trustees and Executors against all risks attending those positions, where the business is conducted by the Solicitors to their Trusts under the supervision of the Corporation, it not being the desire of the Corporation to interfere in any way with the duties of the family solicitor.

The Corporation acts as Trustees for the Debenture Holders in Public Companies.

For terms, &c., application should be made to the General Manager at the Company's Office.

GEORGE PEARSON, *General Manager and Secretary.*

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL SCIENCE, INDUSTRY AND ENGINEERING.

No. 530.—Vol. XXI. FRIDAY, JULY 13, 1888. Price 4d.

NOTES.

On Monday last Mr. Justice Kekewich delivered judgment in the case of Gaulard-Gibbs *v.* Ferranti, ordering that the patent should be declared null and void. The full text of the judgment will be found on another page. Mr. Justice Kay's judgment in the case of the Edison Swan Company *v.* Holland and others has not yet been delivered.

Although it is to us a matter for unqualified regret that vast sums of money should have been transferred from the electric lighting interests—where capital was never more needed than at present—into the pockets of lawyers, who are probably far too shrewd to invest in "A.T." or "B.T." systems, yet we cannot help expressing our admiration for the way in which the said lawyers have defended the interests of their electrical clients. The points with which they have had to deal have often demanded both a very considerable acquaintance with the principles and a firm grasp of the practical details of electric lighting, and in only a very few instances have the counsel on either side failed to rise to the occasion. We trust that we may without impropriety apply the same remark to the judicial bench. The manner in which Mr. Justice Kay has grasped the bearing of the technical evidence has been the subject of remark amongst everyone present in court. This is the more noteworthy in the case of the judges, because, unlike the counsel, they have not the advantage of being coached by the leading witnesses.

We are, however, constrained to make an exception in the case of the opening speech of counsel in the trial of Gaulard-Gibbs *v.* Ferranti. From a purely technical point of view the speech of Sir Henry James is perhaps the most remarkable forensic effort to which the whole history of electrical patent litigation has given rise. We must not venture to comment thereon, lest we should be led into contempt of Court—possibly of a pronounced character.

We understand that negotiations are going on between the Atlantic Cable Companies for an arrangement with regard to rates. The English Companies having always been willing to adopt a shilling tariff for a time, in the hope that it would develop traffic sufficient to pay a moderate dividend, it has remained for the Western Union Company to agree with Messrs. Mackay and Bennett, of the Commercial Cable Company, to adopt this rate. We believe it has not yet transpired whether there are any conditions attached to the proposal or not. It will be seen, therefore, that the matter rests at present very much in the hands of the American Companies, who seem to desire a minimum tariff per message of 5s. This, however, is contrary to the rules of the International Telegraph Convention, and we believe it will be impossible to carry out any such retrograde step. Most of the Atlantic Companies hold concessions, involving adherence to the Convention, from France, and the Anglo-American Company from Germany also, and these companies would certainly not permit such an infraction of the rules they have themselves established at the telegraphic conferences.

The First Commissioner of Works told Sir Henry Roscoe in the House of Commons the other night that to extend the present system of electric lighting throughout the whole of the Houses of Parliament would not cost less than £40,000 per annum. In the absence of detailed information we are unable to check the accuracy of this calculation; but taking the cost of a 16 candle-power lamp, including interest and depreciation charges, at ½d. per hour, the total sum named by Mr. Plunket would suffice for 19,200,000 lamp-hours, or say, roughly, 10,000 lamps burning 2,000 hours per annum. Now we may, of course, be mistaken, but we are inclined to think that 10,000 lamps would be in excess of the actual requirements of the building, and we feel almost certain that the *average* duration of lighting per lamp would be less than 2,000 hours per annum. If Mr. Plunket asks for tenders in the open market, we have little doubt that he will find responsible firms willing to carry out the work at a more moderate figure.

The Society of Arts may well be congratulated upon the remarkable results which have already attended the foundation of the Dr. Mann lectures on Atmospheric Electricity. There can, we take it, be no question that the recent lectures of Dr. Lodge on this subject are a most important contribution to our knowledge of the general principles underlying the phenomena of the thunderstorm. And although the lecturer confined himself chiefly to questions of principle, yet the practical recommendations with which the address concluded ought to be carefully read and pondered over by everyone who is in any way responsible for the protection of buildings from lightning. This is all the more necessary from the fact that the lecturer is driven to the conclusion that such protection is "by no means so easy a matter as the older electricians thought it."

Digitized by Google

A good "earth," high conductivity, and one or more sharply pointed sky terminals were supposed to be the only essential details. This state of ignorance continued until in January, 1886, Prof. HUGHES disclosed the influence of the self-induction coefficient, and insisted on the superiority of flat tape or stranded wire. We need not recapitulate here what are the points upon which Dr. LODGE lays stress, since they will be found on page 306 of our present issue.

As an appendix to these lectures, we are enabled to publish some extremely interesting correspondence which has taken place between Dr. LODGE and Prof. HUGHES on the question of iron *versus* copper for lightning conductors. We do not wish to offer any criticism upon the merits of the controversy in its present stage, but we may perhaps be permitted to point out that the *fact* that a Leyden jar discharge will, under certain conditions, traverse a thin iron wire in preference to a thick copper rod is not in dispute. The real question seems to be whether the experiments of Dr. LODGE or those of Prof. HUGHES approximate most nearly to the more dangerous phenomena of the lightning flash. It is clear that either kind of discharge—that is both the continuous flow and the "impulsive rush," with its accompanying electrical oscillations—may, and do, occur during thunderstorms; and we take it that Dr. LODGE has shown that the latter is by far the more dangerous, and should chiefly be considered when planning the conductors.

WE are also indebted to Prof. HUGHES for calling our attention to a remarkable Paper by Prof. GUILLEMIN which appeared in the *Comptes Rendus* as long ago as 1866, and of which we now print a translation. In the correspondence above alluded to will be found some account of the experiments which Prof. HUGHES carried out in connection with Prof. GUILLEMIN on lightning protectors for use on telegraph lines on behalf of the French Government. It was after Prof. HUGHES had left for St. Petersburg that the experiments described in Prof. GUILLEMIN's Paper were carried out. It is evident that the Professor was considerably astonished at the results obtained, which he regarded as altogether irreconcilable with the law of Ohm.

WE are inclined to agree with the opinion expressed at the meeting of the Association for the Promotion of Technical Education last Saturday, that to delay legislation on this important subject will tend to paralyse local effort, and to indefinitely postpone all action whatsoever in the great towns. It is to be hoped, therefore, that, although it is not among the measures which the Government is pledged to carry this Session, the promised Bill authorising Board and Voluntary schools to establish technical instruction may be reintroduced in the autumn. At the same time, it will be well for members of the Association to take note of Lord ARMSTRONG's criticisms in this month's *Nineteenth Century*, and make up their minds what it is they want. In the title of his article, "The Vague Cry for Technical Education," Lord ARMSTRONG concisely expresses a widespread objection to the Association's somewhat indefinite aims, which as at present propounded are, in his opinion, open to a more serious objection still, namely, that they are directed to the acquisition of knowledge rather than to the training of the faculties. No one, perhaps, is more competent to form a sound judgment on this industrial question, and the article referred to is an opportune and admirable contribution towards its solution.

TO-DAY we are able to complete the text of the Instructions which have lately been issued by the Postal Telegraph Department relating to Mechanical and Electrical Examination of Apparatus before being sent out of the Depôt. The document, as a whole, ought to be of great interest and value to the telegraphic world, seeing that it deals with almost all known forms of appliances used in the operative branch of the profession, and is the result of the most lengthened and most varied experience that any telegraph service, public or private, can possibly have had. It should, perhaps, be mentioned that there are two kinds of tests. The mechanical examination is done by the Department of the Controller of Stores, the electrical examination by the Engineering Department. The latter Department, however, necessarily repeats to some extent the mechanical examination.

THE *Statist* has joined in the general assault on the United Telephone Company, though in a more candid and temperate spirit than has been common with its financial contemporaries of late. Under the heading of "Two Different Telephone Systems" the *Statist* draws a comparison between the National Telephone Company's system in Glasgow and the United Company's system in London, a comparison, we need hardly say, all in favour of the former. The last-named company, however, takes its punishment very philosophically; and, entrenched in its 15 per cent. dividends and the smiles of its shareholders, can afford to defy all criticism. Were it not so, however, there are at least half a dozen points of view from which comparisons such as this are either unfair or beside the mark. In the first place London is not Glasgow, and this circumstance alone accounts for a great deal of difference in their respective demands for telephonic service. That this demand depends in no way on population, as the enemies of the United Telephone Company would have us believe, is demonstrated by their own figures. These figures, if we cared to employ them in that fashion, would prove that while such insignificant places as Ayr, Kilmarnock, Grangemouth, and Hamilton are admirably served, Glasgow, the ideal of telephonic perfection, is, by comparison, far inferior to London. But all such reflections are irrelevant and idle in face of the obvious fact that the provincial companies are struggling to earn dividends, whereas the metropolitan company earns a very handsome dividend without struggling at all. This, at any rate, is the probable explanation; and from a financial point of view it constitutes a justification as well.

OF course, there is the point of view of the public; but we entirely fail to see where it comes into the arguments of the financial press, which is mainly occupied in teaching the United Company how to earn more money, or how to enable its subsidiary companies to earn more. The interests of the public have been advocated on their merits in these pages from the

Digitized by Google

very beginning; but we have always had to admit that by granting patent rights and allowing them to be worked independently of State control the public surrendered its title to complain when those concessions, so long as they last, are employed for profit, and for profit only. Of course it may be urged that the Company would get more profit, as well as credit, by serving the public better; but this apparently is just the point which the Company is not prepared to admit.

In the highly interesting Paper by Profs. Ayrton and Perry on alternate-current electrolysis, which will be found on a later page, it will be seen that under certain conditions the evolution of gas from either or both electrodes may be determined at will. In *The Electrician* of December 16th, 1887 (p. 123), a suggestion was made to the effect that in the case of electrolysis by an alternating current under given conditions of temperature, pressure, current density, &c., there is probably a critical rate of alternation for every electrolyte, the determination of which might be of considerable value in the study of molecular physics. We are, therefore, especially interested to note that Profs. Ayrton and Perry find that the rate of evolution of gas depends in part upon the rate of alternation. We have also before us a further Paper by MM. Chappuis and Maneuvrier, in which the same fact is mentioned. We hope to publish a translation of this Paper next week.

We are happy to see that our recent remonstrance against the use of low candle-power incandescent lamps for street lighting has induced the Barnet Local Board to revise their contract with Mr. Joel, and to substitute 32 candle-power lamps for 16 candle-power. This is undoubtedly a step in the right direction, although we should have been glad to learn that either arcs or at least 100 candle-power incandescents were to be used, as Mr. Joel himself advised. After this the Board called upon Mr. Joel to reduce the contract price, which he very naturally declined to do, remarking that he had already fixed it too low. We think that Mr. Joel is now taking a perfectly correct view.

Leamington.—At the last meeting of the Leamington Town Council it was resolved to accept the proposal of the Midland Electric Light and Power Company to light the exterior of the Town Hall with four arc lamps.

Newington.—At a recent meeting of the Newington Vestry the clerk read letters from several electric lighting companies announcing that they intended to apply to the Board of Trade for provisional orders empowering them to supply the parish with electric light. The communications were sent to the Works Committee for consideration and report.

Royal Agricultural Society's Award for the Priestman Petroleum Engine.—We are pleased to note that Messrs. Priestman Brothers have received the award of a silver medal from the Royal Agricultural Society, for the petroleum engine exhibited by this firm at Nottingham. Probably there is no award of this character which carries with it greater weight than that of the Royal Agricultural Society.

The Institute of Medical Electricity.—We are informed that the directors of the Institute of Medical Electricity (Limited) have taken commodious premises at 24A, Regent-street, with side entrance in Jermyn-street, and are having them fitted with the latest and best appliances for electrical treatment by all known methods. It is expected that the establishment will be opened in a few weeks.

Toulouse.—The electric lighting of the Théâtre du Capitole at Toulouse, which was undertaken by the local gas company, has just started working. It comprises 1,000 incandescent lamps of 10, 16, and 20 candle-power, arranged throughout the theatre on alternate circuits, so that complete extinction of the light is impossible so long as one circuit is intact. Each circuit is run off a 500-light Bréguet dynamo, driven by a two-cylinder 50 horse-power Otto gas engine.

An Electric Organ. — A new electric organ has been erected at the back of the stage of the Burg Theatre, in Vienna, and is connected by a cable with the orchestra, where the key-board is situated. The cable is long enough to admit of altering the position of the key-board within a radius of 30ft. The organ has been built by Messrs. Rieger Brothers, of Jagendorf, and the signals are transmitted from the key-board to the relay lever by five Callaud cells.

Siemens' Potential Dynamometer.—An occasional slight source of error in the well-known Siemens potential dynamometer is pointed out by Herr Isenthal in the *Centralblatt*, No. 16. The damping vane attached to the bell-magnet becomes at times, for reasons best known to itself, electrified, and there is then an attraction between the vane and the damping plates, as owing to the mechanical construction of the instrument the vane is insulated. When the fact is realised, it is, of course, easy enough to get over the defect either by uninsulating the vane or by making it of mica instead of aluminium.

The Lighting of Lambeth.—At the last meeting of the Lambeth Vestry a letter was received from the Assistant-Secretary of the Board of Trade stating that all reference to the parish of Lambeth had been omitted from the proposed South Metropolitan Electric Lighting Order. A notice was received from Messrs. Deacon, Gibson and Medcalf that the London Electric Supply Corporation intended to apply for a provisional order for the supply of electricity for an area which would include the whole of the parish of Lambeth. A similar notice was received from the South Metropolitan Electric Supply Company.

Telephonic Charges at Hull.—At a meeting of the Council of the Hull Chamber of Commerce and Shipping, held last week, a letter was read from the Postmaster-General on the subject of telephonic charges at Hull. He had made calculations, and was convinced "that there is no room at present for a reduction. At the same time I may say that when the patents have expired it may be possible for the department to obtain telephones at a much lower price, and it would then be only right to reconsider the charges for telephone exchange wires, and to give the public the benefit of the reduction." Alderman Seaton considered the reply very unsatisfactory.

The Annual Excursion of the Anglo-American Brush Employes.—The eighth annual excursion and dinner of the *employés* of the Anglo-American Brush Corporation came off with great *éclat* on Saturday, July 7. The party, numbering 146, left Liverpool-street per Great Eastern Railway at eight o'clock in the morning, arriving at Clacton-on-Sea at 10:42. All made the best of their time in boating and bathing, and at 1 o'clock the party adjourned to the Osborne Hotel for lunch. The chair was taken by E. Garcke, Esq. There were also present—Messrs. Mordey, R. P. Sellon, J. Evans, Jackson, Fells, and Paterson. The party arrived in London at 10 p.m., highly delighted with their trip.

Ealing.—At a recent meeting of this Board the clerk read a letter from the West Middlesex Electric Lighting Company,

Digitized by Google

informing the Board of the company's intention to apply for a provisional order empowering them to supply the electric light within the area of the Board's jurisdiction. The chairman said it was for the Board to decide what action they would take in reference to the notice. They had a similar one three or four years ago, he believed, and determined to oppose it. The surveyor said he thought this was an entirely new company. The chairman suggested that the letter should be referred to one of the committees to report upon. It was referred to the clerk to report upon the letter at the next meeting.

The Telephone in the Spanish Colonies.—By a decree May 12 last, the Queen Regent of Spain has set forth the conditions upon which telephone enterprise must be undertaken in Cuba, Porto-Rico, and the Philippine Archipelago. The State is to receive at least 6 per cent. of the gross receipts. The concessions are to last twenty years, at the end of which period everything passes to the State. The telephones, as regards taxes, way-leaves, and hours of service, are to be on the same footing as State departments. The *concessionnaires* will have to guarantee the service, and erect offices open to the public. The maximum charge for places situated within municipal boundaries is 102 piastres (1 piastre = about 5d.). This charge is increased to 204 piastres for flats, and 333 piastres for hotels, clubs, &c. An additional 1½ piastre may be charged for every 100 metres outside the municipal boundaries.

The London Chamber of Commerce and the Proposed Electrical Section.—The following circular has been issued by the London Chamber of Commerce:—Sir: I beg to inform you that a preliminary meeting of the members of the Chamber interested in the electrical trades will be held here (Botolph House, Eastcheap) on the 13th July, at three p.m., to consider the appended agenda, when your attendance is specially requested.—Yours faithfully, Kenric B. Murray, secretary:—Agenda.—1. To consider the formation of the proposed electrical section. 2. To decide upon the number of sub-sections, such as those for telegraph and cable companies, electrical lighting companies, telephone companies, electric locomotion, and manufacturing industries appertaining thereto. 3. To nominate a chairman, and fix a date, for the public meeting to be convened for the formation of a section. 4. To suggest a working committee reqresentative of each sub-section.

The Newfoundland Land Company.—A general meeting was held yesterday of the shareholders of the Newfoundland Land Company, which was an offshoot of the original Newfoundland Cable Company. When amalgamation took place about fifteen years ago between that company, the French Atlantic and Anglo-American Companies, there were no powers in the Memorandum of Association of the latter by which land could be taken over. The Newfoundland Land Company was therefore formed, remaining under the management of Mr. Cyrus Field, Sir James Anderson, and Mr. Weaver, and Mr. Mackay in Newfoundland. The shareholders have now formed a new Board in the hope, as stated in the report, of raising capital for the purpose of exploration and, if possible, developing a profitable enterprise in connection with the large quantity of land owned by the company in the Island of Newfoundland.

Electric Lighting at the Houses of Parliament.—In the House of Commons on Monday last Sir H. Roscoe asked the First Commissioner of Works whether, in view of the serious deterioration of the stone fretwork of the interior of the Houses of Parliament, owing to the corrosive action of the products of combustion of gas, he would undertake to extend the system of electric lighting throughout the building, so as to avoid the evil consequences which attended the present system.—Mr. Plunket said that to extend the present system of electric lighting throughout the whole of both Houses of Parliament would involve a very considerable expenditure, not less than £40,000, for plant. It would, however, probably effect a considerable saving in the annual cost of lighting the Palace. Before making any proposals upon the subject, it would be necessary to consider whether some more economical way of obtaining the necessary current of electricity than that which we now use may be made available.

Progress of Repairs to the Interrupted Australian and Atlantic Telegraph Cables.—We are informed that one end of the Eastern Extension Telegraph Company's original Java-Port Darwin cable has been picked up, and the ship is on the spot endeavouring to secure the other; but a telegram yesterday morning reported the weather bad, causing delay to the operations.——In reference to the interruption of the Direct United States Company's cables we are informed that one repair has been effected in mid-Atlantic in upwards of 2,000 fathoms. In regard to the other interruption 600 miles from Ireland, one end of the cable has been picked up, and the "Scotia" is probably grappling for the other.——The Anglo-American Company's ss. "Minia" has repaired a deep-water fault in the Brest cable, and is now engaged on a repair near St. Pierre.——Both ships in the Atlantic, as well as the "Recorder," engaged on the Australian cable, are probably at the present time encountering bad weather, but we understand the directors look with confidence to the early completion of the repairs of all the cables.

Messrs. Fowler and Co.'s Exhibits at the Royal Agricultural Society's Show.—At the Nottingham Show of the Royal Agricultural Society Messrs. Fowler and Co., of Leeds, exhibited a 12 horse-power compound semi-portable engine, specially constructed for electric lighting. This engine is fitted with Hartnell's automatic expansion gear on both cylinders. As usually constructed, engines of this type have automatic gear only on the high-pressure cylinder; but it is essential that the automatic gear should act on both cylinders if the power given off by each cylinder is to be equal under varying loads. This engine is not only economical but extremely well governed. It is incapable of exceeding by more than 1 or 2 per cent. its mean speed when the load is suddenly removed, and will not fall below the mean speed by a greater amount when the whole load is suddenly thrown on. In practice a small fraction of 1 per cent. variation of speed at once begins to alter the degree of expansion, a result quite unattainable in ordinary governing, but which we need hardly say is highly advantageous in electric light engines.

Renold's High-Speed Steel Driving Chains.—We have recently had occasion to refer to the fact that the use of steel chain driving gear for electric tramcars has come into very general favour. We may now add that the chains most in use are those made by Hans Renold, of Green Lane, Manchester. Referring to a chain of this description on the Bessbrook and Newry Tramway, Dr. Edward Hopkinson writes as follows:—"One of the chains made by Hans Renold was put on July 13th. The locomotive has run about 6,000 miles, drawing trains of 9 to 27 tons gross weight; and yet the chain has not been off, nor has it been tightened—in fact, it shows little sign of wear. This is no doubt due to the new method of oiling, as well as to the strength of the chain." In these chains the studs, links, and blocks are each made of a different class of steel, specially selected for the purpose. The bearing surfaces are particularly hard and smooth, and almost dust proof, and special provision is made for oiling. The links

Digitized by Google

are made in different widths, according to the speed at which the chain is to be run, which may be as high as 1,000 feet per minute.

The Electric Lighting of the Arena at the Italian Exhibition.—The arena of the Roman Coliseum which was opened last week at the Italian Exhibition is lighted for the evening performances by 20 Thomson-Houston arc lamps of 2,000 candle-power each, similar to those used throughout the Exhibition. Instead of using reflectors to shade the lamps from the auditorium and to throw the light upon the arena, the half of each lamp which is turned towards the auditorium is painted on the outside with black enamel paint, and on the inside with white enamel paint. The result of this simple device, due, we understand, to a happy thought of the engineer in charge of the installation, Mr. Ireland, is thoroughly satisfactory. The arena is lighted up quite as much as is desirable for the comfort of the spectators, and the light is perfectly steady, showing in that respect a marked improvement over the lighting for the Wild West performance at the American Exhibition last year, when search lights on the roof were employed, and as the latter were not automatically regulated they not only required the presence of a man on the roof throughout the performance to attend to them, but caused some discomfort to both spectators and performers by occasional flickering.

The St. Catherine Lighthouse.—The lighthouse at St. Catherine's Point, on the southern coast of the Isle of Wight, contains the most powerful electric arc light at present in existence. The carbons burnt in this lamp have a diameter of 60mm. (nearly 2½in.), and the light is estimated at 60,000 candles, which when concentrated by the lenses gives a beam of 6,000,000 candles. The carbons are not circular in section, but fluted. This device promotes the access of air to the centre of the arc; it keeps the carbons cooler, and tends to maintain the centrality of the arc. The lamp is a modified form of the Serrin-Bergot type. There are two dynamos by De Meritens, of Paris, each containing sixty permanent steel field-magnets. The armature is 2ft. 6in. in diameter, and consists of five Gramme rings side by side. The motive power has been supplied by Messrs. Robey and Co., of Lincoln, and consists of three compound engines and boilers, each of 12 nom. horse-power, but capable on a push of working up to 48 horse-power. The engines embody all the latest improvements of this well-known firm, and run at 122 revolutions with remarkable ease and smoothness. The fuel used is gas coke, and the boiler pressure is 150lb. Only two engines are employed for the dynamo, the third being required for the steam siren or fog horn.

Fatal Accident from an Ascending Lightning Stroke.—*Il Telegraphista* gives a highly remarkable account of a fatal accident during a thunderstorm. It appears that in the Isle of Farignana, at a height of 1,000 feet above the sea level, there is a telegraph station, a telephone office, and a semaphore signal post, provided with a lightning conductor. These three lines all make earth in a well. Between 2 and 3 o'clock in the afternoon of October 26, 1887, sparks were seen to be passing from the telephone lines to the walls of the iron building in which the instruments were placed. It appears to have been raining at the time, but no mention is made of any other signs of a thunderstorm. The telephone attendant sent for a linesman named Duran; on his arrival he noticed that the lightning conductor belonging to the semaphore post had been fused at a point where it touched the iron frame of the building. Duran carried in his hand a hammer, with a wooden handle, which was connected to the head by two metal strips. He then touched *the earth portion* of the fused conductor with his hammer, and immediately fell dead. It appears that the unfortunate man, at the moment he touched the wire with the head of his hammer, was in metallic connection with it through the two metal strips, and with the floor of the building through his damp boots. It is suggested that a considerable difference of potential existed between the building on the solid rock and that of the earth, with which they were only in communication by means of the earth wire which had already been fused. When the linesman touched the earth end of this wire a discharge passed through his body from the building to earth. It would, however, be satisfactory to have further details of this remarkable event.

Conversazione of the President of the Society of Telegraph-Engineers and Electricians.—On Tuesday, 10th inst., Mr. E. Graves (President of the Society of Telegraph-Engineers and Electricians) and Mrs. Graves held a reception at the Royal Institute of Painters in Water Colours in Piccadilly, which was attended by a large and brilliant assemblage. The band of the Coldstream Guards performed an excellent programme of chamber music under the leadership of Mr. C. Thomas. Amongst those present were the following:—

Visitors.—Sir Edward and Lady Birkbeck, Captain E. M. Shaw, C.B.; M. Fontaine, Prof. Groves, F.R.S.; Rev. J. Macnaught, Prof. Frankland, F.R.S.; Geo. Berkeley, Prof. Vernon Harcourt, Captain W. J. L. Wharton, R.N.; T. A. Highton, L. W. Courtenay, H. Perigal, Sir P. Magnus, Don Arthuro de Marcontu, Prof. W. Hudson, Dr. Plimpton, Sir A. Blackwood, K.C.B.; Captain Adams, C. Hawksley, G. J. Symons, F.R.S.; J. Wimshurst, Dr. Tison, Wolfe Barry, Dr. Radcliffe.

Members.—Sir W. Gurdon, Sir H. Mance, C.I.E.; Prof. S. P. Thompson, F.R.S.; Prof. G. Forbes, F.R.S.; Prof. J. Perry, F.R.S; Prof. D. E. Hughes, F.R.S.; Alexander Siemens, W. Crookes, F.R.S.; W. H. Preece, F.R.S.; Captain H. Sankey, R.E.; Colonel Hamilton, R.E.; Dr. J. H. Gladstone, F.R.S.; Bernard Drake, Augustus Stroh, E. March-Webb, Major C. F. C. Beresford, R.E.; F. H. Varley, Louis Loeffler, J. N. Shoolbred, J. Hookey, F. T. B. Daniell, C. F. Kierzkowski-Steuart, W. M. Mordey, H. Benest, G. C. Fricker, Dr. Baur, Musgrave Heaphy, Walter T. Glover, Capt. Lugar, Sir D. Salomons, Bart.; Sir Douglas Galton, K.C.B.; Prof. G. C. Foster, F.R.S.; Prof. W. G. Adams, F.R.S.; Prof. W. E. Ayrton, F.R.S.; W. Lant Carpenter, Dr. J. A. Fleming, M.A.; J. W. Swan, C. H. B. Patey, C.B.; Capt. M'Evoy, Major-General Festing, F.R.S.; Dr. J. Hopkinson, F.R.S.; Major-General C. E. Webber, C.B.; R. P. Sellon, C. E. Spagnoletti, W. H. Snell, W. B. Esson, F. Higgins, Dr. Walmsley, Dr. Sleet, Capt. G. W. Addison, R.E.; F. Despointes, J. Farquharson, Ch. Gerhardi, Dr. Obach, R. Waring (Pittsburg, U.S.A.), R. E. Crompton, R. K. Gray, and Shelford Bidwell, F.R.S.

Ilfracombe.—At a recent meeting of the Ilfracombe Local Board the surveyor reported that the Gülcher Company were willing to light the new promenade with twelve 300 candle-power incandescent lamps from sunset till eleven o'clock every night for £360 per year, this to include cost of plant, erection and labour.—Messrs. Laing, Wharton and Down would erect 18 arc lamps, each of 1,200 candle-power (being four for the new promenade, and 14 on the Parade), and light the same from sunset until 11:30 every evening for £450 per year.—Messrs. Nicholson and Jennings would provide the light at the rate of from 1s. to 1s. 2d. per 280-candle power per hour.—Mr. Woodley, who, prior to the last meeting made a verbal offer to the Chairman, now wrote offering to light the new promenade five hours per night for £150 per year; at the expiration of twelve months he would remove the plant on payment of £60, or the Board might take it over for £300.—Mr. Lake pointed out that the price now given was 50 per cent. higher than was named at the last meeting by Mr.

Digitized by Google

Woodley.—Mr. Russell said there was no doubt that if Mr. Woodley would provide the electric light on the terms he stated at the last meeting the Board would be justified in accepting the offer. In reply to Mr. Lake, the surveyor said that he estimated that if lighted by gas the Shelter would require about ten lights at from £10 to £12 each. Mr. Lake said he felt confident that the Shelter could be lit by gas at less than £50 per annum. Mr. Day was of the same opinion, and it was resolved after some conversation that the clerk should ask the gas company the cost of lighting by gas before proceeding further. Mr. Russell proposed that the Board should write to Mr. Woodbury to ask upon what terms they would light the whole town. The surveyor said he had written twice already, but he had not obtained a satisfactory reply. The chairman said he should be sorry to see the gas taken into the Shelter. Mr. Camp thought a price should be obtained both from the gas company and an electric light company, and see which was the better. It was also decided, on the motion of Mr. Russell, to ascertain upon what terms Mr. Woodley would light the whole of the town with electricity.

Electric Light Progress in Austria.—The Vienna correspondent of *Industries* writes as follows:—"Considerable progress is being made in various Austrian towns with electric lighting. The total number of glow lamps now installed in Vienna may be estimated at 18,000, and in addition there are about 1,000 arc lamps in use. A small central station is projected for Neuhaus, in the south of Bohemia, where there will be a total of 600 glow lamps installed, the motive power being supplied by turbines. Consumers will have to buy their own lamps, and pay for the current—not by meter, but at a fixed sum of 15 florins (about 24s.) per annum—for every 16 candle power glow lamp fixed. In Pisek, also a town in Bohemia, a central station is in course of erection for 22 arc and one hundred glow lamps for street lighting; power will be supplied by a 45 horse-power water wheel. The station at Karolienthel, near Prague, which I described some months ago, is in successful operation. There are now three hundred glow lamps in use, and the current is partly supplied direct from the dynamos and partly from Khotinski accumulators. One of the most complete installations in Bohemia is that on the Sophieninsel, in Prague, an island on which is a casino used for public entertainments. This installation has been erected by Herr Krizik, and consists of three Otto gas engines, each of 50 horse-power, and a small gas engine for starting the big engines. There are four disc dynamos, each capable of supplying four hundred lamps. In the assembly rooms of the casino there are fixed five arc lamps, and nine hundred glow lamps; but as there is current to spare, some street lighting by arc lamps will be done from these dynamos. The whole of the plant for this installation, including the handsome electroliers, has been manufactured and supplied by Herr Krizik, who is also the contractor for the lighting. The light is not paid for, not by the amount of current consumed, but by the amount of gas used in the engines, the charge varying from 20 kreuzer to 32 kreuzer per cubic metre, according to the number of lamps in use at a time. The gas for the engines costs 9½ kreuzer per cubic metre, or about 4s. 9d. per 1,000 cubic feet, so that the contractor for the electric light receives a surplus of about 7s. on every 1,000ft. of gas required, and this covers his profit, the payment of wages, lamp renewals, carbons, and other charges standing against the installation."

Barnet Local Board and their Electric Lighting Contract.—A special meeting of this Board was held on Friday last. The Chairman reported that Mr. Joel had attended before the committee on electric lighting and had put it to them that it would be unwise to light the town with incandescent lamps of 16 candle-power, as provided in the contract, specialists being of opinion that lights of this power were unsatisfactory for street lighting. The Board having decided on 16-candle lamps it became necessary to call a meeting to take the matter into consideration. Mr. Joel suggested lamps of 32 candle-power, and a plan had been prepared showing seventy-one lamps as sufficient for lighting the town (the cost of which would be about equivalent to gas) instead of 104 16-candle lamps. Another matter for the consideration of the Board was that Mr. Joel's bond had not been executed.—Mr. Schmidt said the reason the bond was not executed was that Mr. Joel did not want to enter into a binding contract to fix a light which he and other scientists believed would be unsatisfactory and discredit electric lighting.—The Chairman: I do not think that is the way to put it. Mr. Joel contracts to provide electric light of any power which the Board may decide, the price being arranged on a certain basis for the 16-candle lamp. We decided to have these lamps; but there is nothing in the contract, I think, to prevent us having larger lamps if that is desirable.—The Clerk, in reply to the chairman, said the contract and drafts were in London for execution, and he could not therefore produce them then for reference.—Mr. Parsloe: I understand Mr. Joel declines to execute the contract if the Board adhere to 16-candle lamps.—Mr. Schmidt: He does not want to be bound to do something which will discredit electric lighting and be unsatisfactory to the Board. Mr. Tryon: It is a most extraordinary thing that this gentleman, who was introduced to us as the first electrician of the day, should have taken all this time to discover that 16-candle lamps are of no use, and that he should make that an excuse for not signing the contract.—Mr. Marriott: He has been advised not to use 16-candle lamps if he can possibly use larger; the small light has been a failure at other places, and he does not want to have a failure here.—After some further discussion, Mr. Widdicombe said, to bring matters to a point, he would move "That the Board is willing to adopt 32 candle-power incandescent lamps in place of the 16-candle lamps mentioned in the contract submitted, at a price to be agreed upon between this Board and Mr. Joel."—Mr. Schmidt seconded the motion.—Mr. James: If we agree to this alteration, how do we know whether in a short time something else will not be proposed? *The Electrician*, which advises Mr. Joel not to attempt street lighting with 16-candle lamps, says nothing under 50 candle-power should be used.—Mr. Widdicombe: We are going to light our streets more cheaply, but we also propose to give additional light. Light for light, we shall save by using the electric light; the additional cost will arise in providing the town with more light than it has hitherto had.—On the motion being put it was carried by a majority of 6 to 3.—A discussion then arose as to the price of the electric light. The terms agreed upon for lamps of 16 candle-power were £2. 14s. each lamp, as against £2. 18s. 6d. paid to the gas company, and, in addition to the difference in price, Mr. Joel claims in favour of the electric light that it will be kept going for an hour later each night. The contract makes the charge for 16-candle lamps the basis, and Mr. Joel was called into the room and asked if he could not reduce the price now that the Board had agreed to the larger lamps.—Mr. Joel replied that he could not; indeed, he had fixed the price too low in the first instance. Mr. Joel also said he recommended arc lights, but the Board decided to have incandescent.—The Board then adjourned, having first impressed on Mr. Joel the desirability of having the bond and the contract executed without further delay.

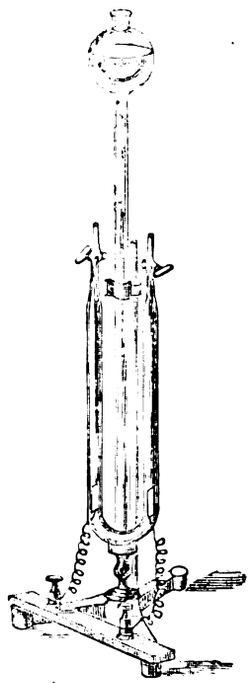
ALTERNATE-CURRENT ELECTROLYSIS.

BY PROFS. AYRTON AND PERRY.

1. The article in *The Electrician* for June 29th on Alternate-Current Electrolysis leads us to mention that, although we have not yet had time to carry out the investigation on this subject that was commenced nine months ago at the Central Institution, one of our assistants, Mr. Raine, in conjunction with Messrs. Lamb, Smith and Priest, three of the third-year students of electrical engineering, have from time to time made detached experiments on this subject. Their results are partly in accord and partly apparently contradict those communicated by MM. Maneuvrier and J. Chappuis to the French Academy, and therefore will probably be of interest to readers of *The Electrician*.

2. MM. Maneuvrier and Chappuis commence by saying that with an ordinary voltameter no evolution is, as a general rule, observed with alternate currents, but the experiments made at the Central Institution have been conducted with an ordinary Hoffmann's voltameter, as shown in the figure, containing a 33 per cent. solution of sulphuric acid, and decomposition has never failed to be produced when an alternate current has been passed through it. The platinum plates are each about $3\frac{1}{2}$



Hoffmann's Voltameter.

centimetres by about 1 centimetre, and the platinum wires inside the voltameter are respectively about 1·6 and 1·9 centimetres long, and about 0·06 centimetre in diameter. On passing an alternate current of about 3 amperes with 10,080 alternations per minute through the voltameter for the first time last November, it was observed that about 10 cubic centimetres of gas came off from each electrode in about three minutes. The gas, as far as could be seen, came off entirely from the wires, and, contrary to what occurs with a direct current, not at all from the plates; the wires became black during the experiment, and the liquid in the voltameter became very hot, showing that there was much decomposition accompanied by rapid recombination of the gases, which produced therefore no visible gas. It was further noticed that a Varley's resistance made of flexible carbon cloth* which was in circuit with the voltameter for adjusting the current strength, became far hotter than if a direct current of 3 amperes was passing through it, the result being produced possibly by a rapid decomposition of the moisture on the cloth, followed by a rapid recombination of the constituent gases.

*Described and illustrated on page 397 of "Practical Electricity."

3. MM. Maneuvrier and Chappuis say that no visible gas is produced at either electrode by an alternate current of from 4 to 5 amperes if the platinum rods exceed 0·1 centimetre in diameter, and are more than 4 to 5 centimetres in length. In other words, their experiments tend to show that a current density of at least $\frac{4}{\pi \times 0{\cdot}1 \times 4}$, that is at least 3 amperes per square centimetre, is necessary to produce visible decomposition. But in our experiments, if we reckon *only one* surface of each platinum plate, the surface exposed was at least $3\frac{1}{2}$ square centimetres, so that in our case visible decomposition was effected with a current density of less than 1 ampere per square centimetre, or less than $\frac{1}{2}$ an ampere per square centimetre if we include both surfaces of each plate. Either, then, it must be assumed that no current leaves the platinum plates, and that all, or practically all, the current goes from wire to wire, or else it follows that an alternating current of much less density than that stated by MM. Maneuvrier and Chappuis can produce visible decomposition of dilute sulphuric acid.

4. In the next experiment the speed of the alternate-current dynamo was increased, and the current rose to $4\frac{1}{2}$ amperes, but the rate of decomposition became much less, tending to show that rate of alternation as well as current density must be taken into account. Again the speed was lowered until a current of 3 amperes passed through the voltameter, but the rate of decomposition was found to be much less than in the first experiment, and curiously enough now the gas was evolved at one electrode about twice as fast as at the other, and on testing the gases it was found that the gas of large volume appeared, on burning, to be pure, or nearly pure, hydrogen, while that evolved at the other electrode was an explosive mixture.

5. No experiments were then made for some months, when, on trying the voltameter again, it was found that when an alternate current was passed through, gas came off freely at one electrode, but none came off at the other. The terminals of the voltameter were then connected with the reverse terminals of the dynamo, but the gas continued to come off only from the electrode from which it came off before. Thinking, perhaps, that the wires of the voltameter had become differently polarised by a direct current having passed through the voltameter on some occasion since the last observations with alternate currents were made, the following experiments were carried out, the letters P and Q referring to the electrodes of the voltameter and A and B to the wires coming from the alternate-current dynamo, B being connected with the uninsulated framework of the dynamo:—A direct current from six accumulators was sent from P to Q for some time (when hydrogen and oxygen came off freely from the respective electrodes in the usual way). The direct current was then stopped, and P joined to A and Q to B, and the evolution of gas observed. P and Q were now disconnected from A and B, a direct current sent from P to Q, then P joined to B and Q to A. Next the direct current was sent from Q to P, and then P joined to A and Q to B. Lastly, the direct current was sent from Q to P, and then P joined to B and Q to A, but in all cases when the alternate current was passing the gas came off solely at one and the same electrode. For the purpose of confirming this curious result, the four combinations just described were repeated over and over again, but always with the same result. It appeared, therefore, that no matter which way a direct current was sent through the voltameter (when hydrogen and oxygen came off freely in the normal way), and no matter which wire from the alternate-current dynamo, after the stoppage of the direct current, was connected to which electrode of the voltameter, the gas came off solely at one electrode. Here, for some reason or other, the voltameter electrodes had acquired a permanent difference, not possessed on the previous occasion, in their power of decomposing gas when an alternate current passed through the voltameter.

6. An interval of some weeks now elapsed, when an opportunity again occurred of making some further observations and the following results were obtained, the direction of the arrow indicating the direction on which the steady current was sent through the voltameter before it was connected to the

Digitized by Google

wires of the alternate-current dynamo. In the first six of the following experiments six accumulators were used to produce the direct current and eleven accumulators in the remainder. The number of alternations per minute in all the experiments was about 10,000, and, as before, the direct current was always stopped, and the voltameter tubes emptied of gas before the alternate current was allowed to pass :—

No. of experiment.	Direction of steady polarising current	Connections for alternate current.	Alternate currents in amperes.	Relative quantities of gas produced at electrodes P and Q.	Nature of gas.
1	P←Q	P to A, Q to B	...	Twice as much at P as at Q	Not examined.
2	P←Q	P to B, Q to A	7	Equal quantities	,, ,,
3	P←Q	P to A, Q to B	7	Equal quantities	,, ,,
4	P←Q	P to A, Q to B	3	Equal quantities	,, ,,
5	P→Q	P to A, Q to B	7	Equal quantities	,, ,,
6	P→Q	P to B, Q to A	7	Equal quantities	,, ,,

Experiments 2 to 6 repeated with same results, but Experiment 1 not apparently reproducible.

Eleven accumulators subsequently employed to produce the steady polarising current.

7	P←Q	P to A, Q to B	Commenced with 5, but the current rapidly increas'd to 7, as if the resistance of voltameter diminished	Equal quantities	Both explosive
8	P←Q	P to A, Q to B	2½	Twice as much at Q as at P	Both explosive
9	P←Q	P to B, Q to A	2½	Eight times as much at Q as at P	Both explosive
10	P→Q	P to A, Q to B	2½	Gas came off at first more rapidly at Q than at P, then gradually it came off at equal rates at Q and P, finally it came off more rapidly at P, so that at the end there were about equal quantities produced at both electrodes.	Both explosive
11	P→Q	P to A, Q to B	2½	All at P	Explosive
12	P→Q	P to B, Q to A	2½	All at P	Explosive
13	P←Q	P to A, Q to B	2½	Nearly all at P	Explosive
14	P←Q	P to B, Q to A	2½	Ten times as much at P as at Q	Gas at P explosive, and little gas at Q, apparently oxygen.

An examination of the preceding fourteen observations led us to the following conclusions :—At the commencement the electrode P was better able than the electrode Q to produce visible decomposition when an alternate current passed. This superiority of P over Q was gradually diminished by sending a direct polarising current from Q to P through the liquid of the voltameter until at experiment 8 the electrode Q had the advantage. This advantage was increased still further at experiment 9. The direct polarising current was now reversed and sent from P to Q, and it will be observed that Q gradually lost its advantage until at experiment 11 it was P that now had the superiority again. Again reversing the polarising current at experiment 13 so that it passed through the liquid from Q to P, we observe that P was gradually losing its superiority.

7. On a later occasion similar experiments to the preceding experiments were carried out with a stronger direct polarising current of 6 amperes, the alternate current being still 2½ amperes, and the effects referred to above were very much more marked. It was now found possible to cause the 2½-ampere alternate current to produce rapid decomposition at either of the electrodes at will, and no visible decomposition at the other electrode, by previously sending for some time the 6-ampere direct current through the liquid from that electrode at which subsequent decomposition by the alternate current was desired. Hence it seems certain that a deposition of hydrogen on a platinum electrode hinders, or even stops altogether, visible decomposition being produced by alternate currents at that electrode, while a deposition of oxygen on the other platinum electrode does not stop, or it may be even favours, visible decomposition. It would further appear from the experiments referred to in § 5 that, although the direct polarising current may be strong enough to produce rapid decomposition, the gases so produced do not affect in a marked way the subsequent relative decompositions produced at the two electrodes by an alternate current, when the alternate current exceeds some particular strength relatively to the strength of the previous direct polarising current.

This communication is not put forward as being in any sense a complete exposition of the phenomena of alternate-current electrolysis, but merely as a fragmentary contribution to a subject which is attracting some attention at the present moment.

UNIPOLAR INDUCTION.—VI.

BY G. W. DE TUNZELMANN, B.SC.

(Continued from page 263.)

The other experiments mentioned were performed with the apparatus shown in Fig. 19. Two ebonite discs, *a g b h* and

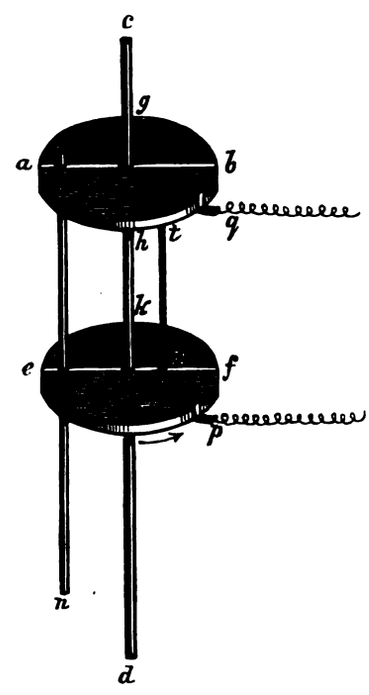


FIG. 19.

a g b h and *e k f m*, ebonite discs having their peripheries encased in brass bands; *c d*, a metallic axis to which they are fixed; *a b* and *e f*, brass bands connected at *a* and *e* with peripheral bands, but insulated from them at *b* and *f*, and from the axis; *t p*, a movable brass rod connected with *a b* and *e f*, and capable of sliding along them; *s n*, a magnet not in connection with any of the metal work; *p* and *q*, contact springs in connection with galvanometer circuit.

e k f m, of equal dimensions, having their peripheries encased with bands of brass, were pierced at their centres and attached to a metallic axis *c d*, about which they could be made to rotate. Two brass bands, *a b* and *e f*, were fixed to the discs and connected at *a* and *e* with the peripheral bands, but were insulated from them at *b* and *f*, and also from the axis. A magnet, *s n*, was passed through the two discs without being connected with any of the metallic portions of the apparatus. One of these discs was placed at the height of the south pole of the magnet and the other in the centre. A brass bar, *t r*, was made to

Digitized by Google

connect the bands $a\,b$ and $e\,f$, and its distance from the axis could be varied at pleasure by sliding it along the bands. Connection with the galvanometer circuit was made by means of two contact springs p and q pressing against the peripheral brass bands.

When the apparatus was made to rotate about the axis in the direction shown by the arrow, a current was produced which flowed through the galvanometer from q to p. Edlund then concluded from his theory that for a given speed of rotation the direction of the current would be independent of the position of the bar $t\,r$, and this he found to be the case. According to the theory which I have adopted in these Papers the same result would evidently follow, for the induction takes place in the fixed portion of the galvanometer circuit, and therefore the position of the bar $t\,r$ cannot possibly have any influence on the E.M.F., and the slight change in the resistance due to the inclusion of a larger or smaller portion of the bands—namely, the portions between b and t and between f and r—will be too small to be appreciable. Neither of these experiments can, therefore, be considered as giving any confirmation of Edlund's assumptions.

Edlund then proceeds to consider the objection that might possibly be urged against his theory, that according to it a cylindrical tube rotating about its axis would exert an electro-dynamic action similar to that of a coil through which a current is passing. This would not be the case, as he points out, if the electric current consists in the transference of equal quantities of positive and negative fluids in opposite directions, as in that case the two fluids being carried with the same velocity in the same direction would neutralise each other's effects.

To explain the absence of any sensible electro-dynamic effect on the hypothesis that the electric current consists in the translatory motion of a single fluid in one direction, Edlund restates his theory of the electric current previously set forth in his "Théorie des Phénomènes Electriques" (Kongl, Svenska-Vetenkaps-Akademiens Handlingar, Vol. XII.). He points out that the phenomena of optics have led to the assumption that the æther is attracted by ponderable matter. "A material body," he says, "condenses the æther between its molecules until the attraction exerted upon an æther molecule situated within the body becomes equal to the repulsion exerted by the already condensed æther upon the same æther molecule. When this point is reached, the material body is no longer in a position to put in motion the external molecule of æther. Besides that quantity of æther which may be regarded as connected with the body's own molecules, there exists free æther between those molecules, and the quantity of free æther contained by the entire body must be equal to the quantity of æther contained in a volume of vacuous space equal to that of the body. This is what takes place as long as the body is at rest. If, on the contrary, the body is put in motion with the æther which it contains, not only the repulsion of that æther, but also the attraction of the molecules belonging to the body upon an exterior æther molecule at rest is modified, and that in virtue of the established principle that *every thing that takes place or is effected in nature requires a certain time.*"

"It does not, however, necessarily follow," he says, "that the modification which the attraction between the material molecules and the exterior æther molecule undergoes in consequence of the motion must be equal to the modification of the repulsion between the æther molecules contained in the body and the same exterior molecule." On the contrary, he maintains that the action between different kinds of molecules must be different also in this respect.

He then considers the following case:—Let an element, d, of a circuit (Fig. 20), containing a quantity, m, of free æther, and m_0 of condensed æther, be supposed to move with the velocity h in the direction shown by the arrow. Let m_1 be an exterior æther molecule at rest, and let the angle between the straight line $d\,m_1$ and the direction of the velocity be θ, and let $d\,m_1 = r$. Then he has shown, "Théorie des Phénomènes Electriques," that the repulsion between m and m_1 is

$$-\frac{m\,m_1}{r^2}\left(1 - a\,h\cos\theta - \tfrac{3}{4}\,k\,h^2\cos^2\theta + \tfrac{1}{2}\,k\,h^2\right),$$

and the repulsion between the condensed æther m_0 and m_1 will be

$$-\frac{m_0\,m_1}{r^2}\left(1 - a\,h\cos\theta - \tfrac{3}{4}\,k\,h^2\cos^2\theta + \tfrac{1}{2}\,k\,h^2\right).$$

Using a_1 and k_0 to denote new constants, the attraction exerted upon m_1 by the material molecules can be expressed by

$$+\frac{m_0\,m_1}{r^2}\left(1 - a_0\,h\cos\theta = \tfrac{3}{4}\,k_0\,h^2\cos^2\theta + \tfrac{1}{2}\,k_0\,h^2\right).$$

The sum of these three expressions will give the whole action of the element d on the æther molecule m_1.

The ratios of a to a_0 and k to k_0 may be determined from the consideration of the production of electricity by friction, when the æther molecules must be supposed to pass from the rubber to the body rubbed, or *vice versa*. This passage must arise, he considers, from the repulsion exerted on them by the body in motion being in some way modified by the motion itself.

Now if

$$\frac{a_0}{a} = \frac{k_0}{k} = \frac{m + m_0}{m_0},$$

the sum of the three expressions giving the action of the moving body on an æther molecule becomes equal to $\frac{-\,m\,m_1}{r^2}$, or the repulsion would have the same value as before the body was put in motion. Therefore, a_0/a and k_0/k could not have exactly the same value.

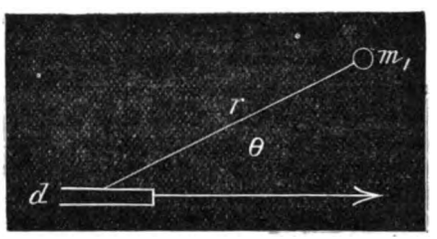

FIG. 20.

This applies to cases when bodies are in contact, or r infinitely small. If the two bodies are at a finite distance from each other, it is impossible to produce a sensible development of electricity by the movement of one of them, and therefore a_0/a and k_0/k must become sensibly equal to $\overline{m + m_0}/m_0$ when r has a finite value.

If, therefore, a body is put in motion together with the æther, both free and condensed, which it contains, its action upon a motionless exterior æther molecule at a given distance will be nearly as great as if the body were at rest at the same distance. When the exterior æther molecule is itself in motion, and therefore forms an element of an electric circuit, similar reasoning leads to the same results.

A cylindrical tube made to rotate about its axis will therefore exert little, if any, electro-dynamic action; in fact, the action of the currents due to the æther being carried in the direction of the rotation will be neutralised by the opposite electro-dynamic action produced by the motion of the proper molecules of the body in the same direction. Edlund states that M. Lemström has succeeded in showing that a rotating cylinder is capable of producing a real, though excessively feeble, electro-dynamic action.

M. Lemström made a pasteboard cylinder filled with air rotate rapidly round a cylinder of soft iron, and he found that the magnetic condition of the iron was modified by the rotation.

(To be continued.)

Meeting of the American Association for the Advancement of Science.—The American Association for the Advancement of Science holds this year its thirty-seventh meeting at Cleveland, Ohio, from Wednesday morning, Aug. 15, to Tuesday evening, Aug. 21. For all matters relating to membership, papers, and business of the association, the permanent secretary should be addressed at Salem, Mass.

PROTECTION OF BUILDINGS FROM LIGHTNING.

BY PROF. OLIVER LODGE, D.SC., F.R.S.

(Concluded from page 276.)

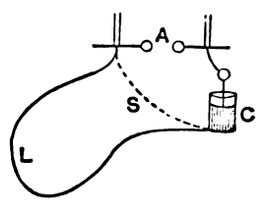
Experiments on Overflow of Jar.

Another way of making these electrical surgings more conspicuous is by their effect in causing a jar to overflow, *i.e.*, to spark round its edge. The overflow of a common jar is, in fact, very like a lightning flash, for it is a discharge direct between two coatings. That is just what a lightning flash is. There is ordinarily no conductor present except the two coatings—the clouds and the earth. I found a curious remark in Franklin* about the overflow or fracture of Leyden jars. He found that when one broke from overcharging a great number went together, *and also that the spark in the ordinary circuit did not fail.* He was led by this observation to doubt if the breakage of the jar was really due to a discharge of the electricity through it, and he surmises that it may be due to a sudden expansion of air bubbles in the interior, suddenly relieved of the strain.

No doubt he is wrong there, but the observation of the facts is good and noteworthy. We will repeat the experiment. It is not necessary to burst the jars ; overflow round the edge is just as good, and cheaper. The overflow experiment can be put into a variety of forms ; perhaps it will be sufficient if I show the simplest.

Fig. 9 shows the arrangement. It consists in nothing but establishing the connection between the machine and one or both of the coatings of a jar, through a long wire instead of through a short one as usual. If one connects the jar, C, by the dotted line, it does not

Fig. 9.



overflow until the spark length, A, is very great ; but with a long lead, L, to make the connection, a very short spark at A will cause the jar to overflow or discharge round its edge.

Here are a few numbers. The jar is one of the gallon jars, with the glass fully three inches above the tinfoil, so that when it overflows the spark has to strike along fully six inches of glass. When L is the thick No. 1 copper circuit round the room the jar overflows every time an A spark occurs, even though the length of this A spark is only ·64 of an inch. Short circuit out the long lead, as shown by the dotted line, and the jar refuses to overflow until the A spark length has been increased to 1·7 ; and when it does overflow now the violence is very considerable. Remove short circuit again, and the jar overflows in ever so many places at once with great violence, a perfect cascade of flashes leaping round the edge. Bring the A knobs nearer together, and the overflow does not wholly cease till their distance apart is again ·62.

On another occasion one got for the A spark length sufficient to cause overflow of jar :—

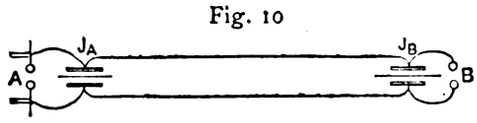
·56 with the long lead.
1·7 with an ordinary short wire.

With a small pint jar, and a less height of glass above its coatings, I took the following readings :—Length of A spark sufficient to cause overflow—

·67 with iron wire round room.
·52 with copper ,, ,,
1·40 with short circuit.

Fig. 10 shows very well, in a diagrammatic fashion, the effect of long leads in causing a jar to overflow, or of course to burst if the glass edges are too tall for the thickness and homogeneity of the glass to stand.

Fig. 10



A are the machine terminals, B those of a discharger, and J_A and J_B are two jars connected up by fairly long leads. Now of course sparks may be obtained either at A or at B, one as easily as the other, and one of the jars is liable to overflow, but not both. It is the jar J_B which overflows when a spark occurs at A. It is the jar J_A which is made to overflow by a spark at B. It might be thought that if the B knobs were fairly near together, a spark at A might precipitate a spark at B instead of making J_B overflow ; but it is not so. The event is not indeed impossible by any means, if the B knobs are pretty near together; but it is easier for the jar to overflow by direct discharge between its coatings over a space of some six inches than it is for it to discharge through the wire and rods of the discharger and an air-space of an inch or even less. It is not easy to help a jar to overflow by discharging tongs ; even a foot of conducting wire is a great obstruction to the passage of the flash ; it greatly perfers direct discharge through air unobstructed by the self-induction confinement of a conductor.

This is also illustrated by the extraordinary length of insulating surface which is found necessary in the Leyden jars supplied to Holtz and other such machines, and by the fact that such jars often flash even over a foot instead of through a few inches of air space led up to by the proper discharging knobs. Though indeed it must be noticed, as it was by Franklin, that the overflow of a jar by no means necessarily robs the proper circuit of its flash. The two things occur together. It is usually the spark which causes the overflow. Perhaps one may say that the case of discharge direct between coatings without any conductor, accounts in some measure for the extraordinary length and unexpected paths of some lightning flashes.

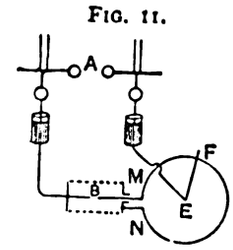
These electrical oscillations and overflows, which it is thus easy to set up in a charged conductor, manifestly explain what is known as the "return stroke." I pointed out in Lecture I. that the ordinary explanation of the return stroke, the recovery of electrical equilibrium disturbed by static induction, was by no means able to account for effects of the least violence ; but this fact, that a discharge from any one point of a conductor may cause such a disturbance and surging as to precipitate a much longer flash from a distant part of it, at once accounts for any "return stroke" that has ever been observed.

It is for this reason that I think it possible a tall chimney or other protuberance in one's neighbourhood may be a source of mild danger ; inasmuch as if it is struck it may be the means of splashing out some more discharges to other smaller prominences, which otherwise were beyond striking distance. It is in this way, also, that I imagine multiple flashes, such as those referred to in Lecture 1, are produced. I liken them to the cascade of flashes rushing over the sides of a jar, when connected up with a long lead, and when the A spark is pretty long.

Experiment of the Gauze-House.

Finally, we have to ask is it possible for the interior of a thoroughly enclosed metal room to be struck ; or, rather, can a small fraction of a lightning flash find its way into a perfectly enclosed metal cavity ; for instance, a spark strong enough to ignite some gun-cotton in a metal-covered magazine which might happen to be struck ?

Fig. 11.



It is not easy, but it can be done ; at least under such conditions as are likely to obtain in practice it can be done. My friend Mr. Chattack, to whom I am indebted for much kindly assistance and suggestion, has made the experiment in the form shown in Fig. 11.

A metal gauze cylinder, with tin-plate ends, has a couple of conductors, one soldered to each end, protruding into the interior, so as to approach very near each other, and these are the conductors put into the path of the discharge. If both conductors are entirely enclosed in the metal chamber, we have not yet succeeded in getting a spark between them ; but if either of them protrude any portion of their length outside the chamber, then sparks in the chamber can be obtained.

In Fig. 11 the conductor N M B is shown thus protruding, penetrating the chamber through a small glass tube near M, but soldered to it near N. E F is a movable arm or radius, making contact with this conductor. If contact is made near N, it takes a very strong A spark to give any spark at B inside the gauze cylinder ; but as the contact is shifted towards F or M it becomes very easy to get a small spark at B.

* "Franklin's Works," by Sparks, 1840. Vol. V., page 475.

Digitized by Google

The application of this to powder magazines is that if any conductor (like a gas pipe) pass out of a building before being thoroughly connected with its walls, it is possible for a spark to pass from something in the interior of the building to this conductor whenever a flash strikes the building, even though perfectly connected outside. We thus find that the complete and certain protection of buildings from lightning is by no means so easy a matter as the older electricians thought it.

In many cases we may be content to fail of absolute security and be satisfied with the probable safeguard of a common galvanised iron rod or rope. But for tall and important buildings, for isolated chimneys and steeples, and for powder magazines, where the very best arrangement is desirable, what is one to recommend? I prefer to call attention to principles rather than to advocate any particular nostrum; but inasmuch as my present opinion is not likely to carry any undue weight, there is no harm in my saying that I see nothing better than a number of lengths of common telegraph wire. I think a number of thin wires far preferable to a single thick one, and their capacity must be increased when possible by connecting up large metallic masses, such as lead roofs and the like. But the connection should be thorough, and made at many points, or sparks may result. Balconies and other prominent and accessible places should not be connected.

The earth should be deep enough to avoid damage to surface-soil, foundations, and gas and water mains. As to the roof, I would run barbed wire all round its eaves and ridges, so as to expose innumerable points, and the highest parts of the building must be specially protected; but I would run no rods up above the highest point of the building, so as to precipitate flashes which else might not occur, in search for a delusive area of protection which has no existence.

The conductors must not be so thin as to be melted or deflagrated by the flash, but really melting is not a very likely occurence, and even if it does occur the house is still protected; the discharge is over by the time the wire has deflagrated. The objection to melting is twofold; first, the red-hot globules of molten metal, which, after all, are not usually very dangerous out-of-doors; and, secondly, the trouble of replacing the wire. I should be content to put up a great number of telegraph wire conductors, and wait till one is melted, before thinking too much of the likelihood of such an occurrence. The few instances ordinarily quoted of damage to lightning conductors by a flash do not turn out very impressive or alarming when analysed.

In conclusion, I trust that the men of experience in these matters who are present will consider the facts and suggestions I have brought forward as objects worthy of attention and further inquiry, and will study them in the light of their experience.* But as to the quack recipes and dogmatic statements which I may incidentally and without authority have provisionally given, there is no need for me to ask practical men to treat these with the contempt they no doubt deserve.

THE PROTECTION OF BUILDINGS FROM LIGHTNING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The enclosed letters, which I received from Prof. Hughes shortly after the delivery of my lectures at the Society of Arts, are of general interest, and, having obtained his consent, I therefore ask you to publish them as a sort of appendix to the lectures which you have reprinted.

The experiments he describes are conducted on the "steady strain" principle, rather than on the "impulsive rush" method; for any practicable motion of discharging tongs must be regarded as infinitely slow. For the rest, the experiments are like mine on the "alternative path," except that instead of measuring directly the E.M.F. needed to drive a current through a conductor by observing the length of spark corresponding to it, these experimenters make use of a fine wire as their shunt circuit. [I also have experimented in this way, but found it less rapid and convenient in practice.] The slight divergencies of results are interesting. The letters, I think, speak for themselves, and require no further comment. I would certainly have quoted these experiments in my lectures had I known about them, as I ought to have done.

* At the second lecture I learnt that some experiments on lightning protectors, something like those of mine on "the alternative path," had been made previously by Prof. Hughes and M. Guillemin ("Address to Telegraph-Engineers"). Also I find that Dr. Hertz has made experiments on electric oscillations very like those of mine on "the surging circuit" (Wied. *Ann.*, 1887). In a subsequent communication I hope to notice some of the observations of Prof. Hughes.

Just one remark about one of the concluding sentences in the third letter, "however much we may doubt the Wheatstone-bridge method I employed." Any observations of mine derogatory to Wheatstone-bridge methods as applied to lightning-conductor-testing relate solely to the time-honoured practice as learnt by schoolboys from what seems time immemorial. The methods with alternating currents devised by Prof. Hughes stand on a different footing altogether, and if only the frequency of alternation were made great enough (I fear, however, that the telephone would be then giving a note immensely too high to be audible), they might very well be used to give the information about any conductor which is needed. But, perhaps, a Leyden jar system of testing would be found easier. Though, indeed, it by no means follows that the path chosen by a weak spark will also be chosen by a strong one. I can get sparks to jump in altogether different places according to their strength, nothing at all being varied except energy of spark.

Perhaps I may take this opportunity to refer to an altogether different matter. One of the facts to which I call special attention in the lectures is the mode in which currents increase and decrease in a conductor—changes commencing always at the outside and penetrating inwards, so that alternating currents tend to keep to the outside altogether. I have spoken as if this fact were discovered independently by several persons working from various points of view, and expressing the result each in a different fashion. I am now informed that Mr. Oliver Heaviside published this fact, as deduced mathematically by himself, a year before Prof. Hughes' experiments, which illustrated it and brought it into prominence, were published, and also before Lord Rayleigh had written on the matter; and that to Mr. Heaviside, therefore, the priority is distinctly due. I have no opportunity just now of verifying this statement, but I have not the slightest reason to doubt it; and probably to readers of *The Electrician* it is a familiar fact.

I preferred to leave the matter vague, because it is no part of my business to play the historian of science, and because questions of priority concerning recent discoveries are apt to be burning ones. That is no reason for shirking their treatment when one has a full knowledge of the matter; but it is precisely that essential full knowledge that I at present lack. It is a matter easy to verify, however, and before the lectures are republished I shall hope to verify it.

The phenomena connected with alternating currents are peculiar and often surprising, and I believe there is no person now alive who has anything like the intimate familiarity with their idiosyncrasies that Mr. Heaviside has attained to. Considering the extraordinary magnitude of the leaders of physical science at the present time, this is a strong thing to say; nevertheless, I believe it would be heartily endorsed by all those most competent to judge.

The experimental genius of Prof. Hughes is a matter of notoriety; the mathematical genius of Mr. Heaviside is equally striking, and will shortly, I expect, be as cordially recognised.—Yours, &c., OLIVER J. LODGE.

University College, Liverpool, July 1, 1888.

The following are the letters referred to above:—

"108, Great Portland-street, W., March 17, 1888.

"Dear Prof. Lodge: I was very much interested in the beautiful experiments you made in your lecture at the Society of Arts this afternoon, and I regret that I was unable to be present at your first lecture, which no doubt would have enabled me more completely to understand your present view of 'lightning conductors.'

"The great portion of the experiments showed by you yesterday entirely agree with those obtained by Prof. Guillemin and myself, whilst those relating to the use of iron and copper seem to disagree. Your experiment certainly demonstrated your view, whilst mine seems to me to demonstrate just the opposite.

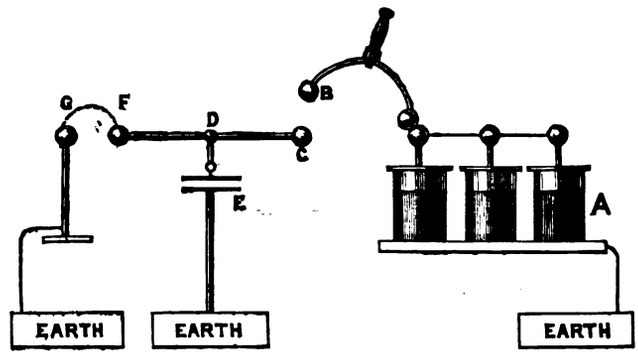
"In 1864 the Administration des Lignes Télégraphiques of France, through the Commission de Perfectionnement, of which

Digitized by Google

Prof. Guillemin and myself were members, charged us with the mission of verifying experimentally the merits of different lightning protectors in use for the protection of the telegraph instruments from lightning. These experiments were carried out at the laboratory of the Ecole de St. Cyr, of which Prof. Guillemin was the Professeur de Physique.

"We tried to imitate as nearly as possible the conditions which occur in practice.

"The general idea of our experimental arrangement was the following:—



"In order to have a powerful source of electricity at high tension we made use of a large battery, A, of 12 large jars, and as we found it took too long to charge these with the ordinary electrical machines, we used a powerful Ruhmkorff coil, which would give a spark of 15 centimetres. The jars were charged to a fixed degree, and could be discharged through our apparatus by means of the universal discharger B. An insulated rod of brass, C D F, served to conduct the charge to the experimental protector E, and by a derivation, F G, to earth. At G F we could place a telegraphic electro-magnet, a fine iron wire, or an electrometer, the object being to try and save the fine wire at G F from destruction by the protective action of the protector E.

"We found that with a high charge no protector would entirely protect G, even if a small air space intervened between F and G; and we also found that if D was directly connected to earth by a copper rod of one centimetre diameter, there would still be sufficient electricity pass D to G to burn a fine iron wire.

"This result proved that we could not in all cases expect absolute protection from any known protectors.

"By gradually diminishing the charge we arrived at a point where we could make comparative experiments.

"The protectors have all a small air-space, in order not to weaken the ordinary working current.

"The received idea that two plates with innumerable points near each other would protect in a far greater ratio than simple plates separated by a thin sheet of paraffin paper or gutta percha was disproved; for the simple flat plates known as the 'American protector' were invariably better than those with points. The plates formed a small condenser, the surfaces of which could be brought far nearer to each other than is possible in practice with points.

"In a report which I made as reporter, I pointed out all these experimental facts, and it was published in the *Annales Télégraphiques*, 1865, and I again gave these facts in my inaugural address to the Society of Telegraph-Engineers, January 28th, 1886, and published in their *Journal*, No. 60, p. 17.

"We tried numerous experiments as to different kinds of wire at E, and if we placed a very large condenser at E in place of a protector it seemed to have a far greater effect.

"Having been called to Russia I was unable to continue these experiments at that time, but Prof. Guillemin having taken a great interest in them, he continued them, and published his results in the *Comptes Rendus* (I forget what date). He found that if he united D to earth by a thin flat plate, even tinfoil, a very large measure of protection had been obtained, and that flat conductors were evidently superior for a sudden charge of high-tension electricity. He supposed that this effect was due to its electrostatic capacity thus forming a specie of condenser. Later experiments by myself have pointed out the advantage of the flat conductors, but my results lead me to suppose that, in addition to the reasons of Prof. Guillemin, it is because a flat conductor has far less self-induction.

"The experiments which you showed yesterday also seemed to point out the advantage of flat conductors, and your views seemed to agree with those of Prof. Guillemin, and you have experimentally proved this in the beautiful experiment where you show the different results obtained from a tinfoil sheet conductor where it is arranged so as to have more or less self-induction.

"The greatest and perhaps the only difference in your results was the superiority of iron over copper. The methods used by you fully demonstrated it, and it also resembled the method used by Prof. Guillemin and myself, except that we had one large battery discharged to earth, whilst you seemed to have two batteries, one at A and the other at G. If I am correct, there may be some peculiar phenomena due to our different arrangements.

"That self-induction is injurious to rapid transmission of electrical currents of low potential is shown in practice by their different behaviour. Practice has shown that copper alone is suitable for long-distance telephony and telegraphy, and I still believe that the same marked difference holds good with high-tension currents for the same reason.

"However, there is nothing like experiment to prove a fact, and I shall read your paper and future experiments on this subject with the greatest interest, knowing that you are a most careful experimenter. The subject is one of vast importance, and it is astonishing that with the innumerable experiments that have been made, from Franklin to Faraday, in all countries, and with apparent irreproachable methods, there should be still such a wide division of opinion as to the merits of round or flat conductors and of iron or copper.

"Excuse this hastily-written letter, which does not require an answer, and believe me, with the highest esteem both for yourself and your researches, sincerely yours,

"D. E. HUGHES.

"Prof. O. J. Lodge, D.Sc., &c., &c.,
University College, Liverpool."

"108, Great Portland-street, London, W.
"March 20th, 1888.

"Dear Prof. Lodge: Many thanks for your kind letter, which I have received this evening.

"My letter was written not with a view to publication but as a friendly discussion on a subject in which I was extremely interested several years since. If, however, you think there is anything in it worthy of publication as an appendix to your Paper I can have no objection, leaving to your judgment to select the portion you deem worthy of publication.

"You believe that the difference between our results is due to the use of a discharger, and this may explain the difference.

"The object of Prof. Guillemin and myself was to send a powerful charge through a wire with the utmost possible suddenness.

"By the use of the discharger we could charge our battery to the desired point, then disconnect the Ruhmkorff, and then bring our discharger as suddenly as possible in connection with the experimental apparatus.

"It is evident that we could never do this with the rapidity that we desired, as the spark would jump across the air before full contact was made. We believed, however, that we came nearer than if we had a fixed distance, allowing the charge to spark across the interval, as then our experimental apparatus or any change made in it seemed to have an influence on the *time* discharge of the battery. It is so long, however, since these experiments were made that I cannot discuss this point, and probably your views or method may be more in accordance with the actual conditions of a sudden discharge than ours were.

"We certainly agree in our results and views on the most important points. For I quite agree with you that Wheat-

Digitized by Google

stone's bridge, or any apparatus used for steady currents, does not indicate what passes at the first moment of contact.

"Judging from our experiment where we could not protect the fine iron wire by a direct thick copper, iron, or any short metallic contact, and from later experience on self-induction with low-tension currents, I believe that at the very first instant all bodies offer an infinite resistance, copper being no better than air. I believe you also take this view, as you well illustrated it by the flow of water, the hammer blow, inertia, &c.

"The effect is so marked with discharge from a good Leyden jar battery that it becomes a serious question if any lightning conductor yet made could convey the whole of a lightning discharge quietly to earth without its seeking other channels through substances having an infinitely higher ohmic resistance; and the whole question would be discouraging were it not for the fact that we have undoubted proof that lightning conductors do protect in spite of the experiments cited.

"I have tried to gain some exact information from the Report of the Lightning Rod Conference, 1882, in the numerous cases there cited, and I find that in most cases the rods have protected, but many have failed, mostly from bad earths; but numerous cases are there cited in which rods were melted, both of copper and iron—in fact, the cases cited do not show any marked preference for either metal, except that there seems a stronger testimony in favour of Sir W. Snow Harris's copper tape conductor than any other.

"It is quite possible that all the researches that have been made have never yet approached the true condition of things. Evidently experiments made with simple sparks from machines never approach the true conditions. A very large Leyden jar battery or powerful condenser seems nearer; but even this must be weak compared with a true lightning discharge. But still it ought to teach us, as it has done in your case and others, myself among the number, that an enormous inertia or apparent resistance is offered by the best of metallic conductors at the first instant of discharge.

"I shall read your experiments and views on this interesting subject as soon as they appear in print, and I hope that your new series of experiments will clear up any mystery, if there is any. With many thanks for your kind letter, and with best wishes, believe me, sincerely yours,

"D. E. HUGHES.

"Prof. O. J. Lodge, D.Sc., &c., &c.,
University College, Liverpool."

"108, Great Portland-street, W., March 29th, 1888.

"Dear Prof. Lodge: Excuse me for writing again, but I find that I have not fairly represented Prof. Guillemin's views—due to only reading an abstract. I have found his Paper entitled "Sur la Décharge de la Batterie Electrique et sur l'Influence de la Configuration des Conducteurs," *Comptes Rendus*, 1866, pp. 1,083 to 1,085.

"In this Paper he believed the advantage of thin flat sheets to be due to the mutual reactions of each portion of the current on each other, and although he does not use the term he evidently means self-induction.

"I find also that he demonstrated this, noting the difference of several copper wires when twisted together or separated as in a sheet; in fact, an identical result which I obtained later with low-tension currents and Wheatstone's bridge (No. 60, p. 15, *Journal* Society of Telegraph-Engineers, 1886). Thus, he did not attribute the advantage of sheet conductors to electrostatic or mere surface conduction. The experiments made by Prof. Guillemin and myself, which I have already mentioned, were made in 1864, but not published until 1865 (*Annales Télégraphiques*, 1865, pp. 290 to 302, Tome VIII.).

I believe that Sir W. Snow Harris also attributed the advantage that his experiments showed in sheet conductors to the same reason and not to mere surface conduction, as I had previously read, for I find in an abstract of his Paper, 1843, published in "Report of the Lightning Rod Conference, 1882," p. 86, these words:—'He says the beneficial effect of superficial conductors appears to depend on the removal of the electrical particles further out of the sphere of each other's influences.'

"This evidently means the same explanation as given later by Prof. Guillemin, and still later by myself in my Paper on "Self-Induction," so in justice to them both I feel it my duty to point these out to you; and I find now that however much we may doubt the Wheatstone bridge method I employed, it certainly gave identical results for a similar experiment with those obtained by sudden discharges from Leyden jar batteries. I have suggested to the editor of *The Electrician* that he should translate and reprint Prof. Guillemin's remarkable Paper, as it would be only justice to him, as I know he suffered severely from the sneers of Messieurs *les Savants* on the publication of his Paper.

"Do not trouble yourself to reply to this, as my only object is to correct my remarks as to Prof. Guillemin's views made in my first letter.—With best wishes, sincerely yours,

"D. E. HUGHES."

The following is a translation of the Paper referred to by Prof. Hughes in his last letter to Dr. O. Lodge:—

LEYDEN JAR DISCHARGES AND THE INFLUENCE OF THE SHAPE OF CONDUCTORS.*

Some lightning-guard experiments, conducted last year by MM. Hughes, Bertsch and myself at the instance of the "Commission de Perfectionnement des Lignes Télégraphiques," afforded us an opportunity of observing a phenomenon which it seemed to me could not be reconciled with the laws of electric conductivity. A continuous copper wire did not conduct perceptibly better than a similar wire into the circuit of which a lightning-guard of the point pattern had been introduced. I now present to the Académie des Sciences the result of researches undertaken by me with a view of ascertaining to what extent this phenomenon really does deviate from the ordinary law.

According to Ohm's law, the intensity of a stable current is independent of the surface of the conductors. My experiments show that in the case of Leyden jar discharges (where the current is variable and never sensibly steady) increasing the surface of the conductors facilitates the passage of the discharge.

To show this, I arranged two conductors in parallel so that they should be simultaneously traversed by the discharge from a large 6-jar battery, having a total condensing surface of about 1 sq. m. One conductor was an iron wire, ·1mm. in diameter, and of variable length; the other conductor was a thin sheet of tin, 2 metres long and 6 cm. broad, insulated on a glass table. This conductor was altered in shape without alteration of cross-section. The effect of these alterations could be gauged by the length which could be given to the iron wire without its being melted.

The first thing I did was to arrange matters so that the sheet of tin took a sufficient proportion of the discharge to prevent 15cm. of the iron wire attaining red heat. Then the sheet was bent back upon itself lengthways, diminishing the surface without alteration of length or cross-section; the iron wire then became dull red. If the surface of the sheet was still further reduced the iron wire fused along its entire length. The two conductors were then put in series, and the tin sheet still had the best of it.

This phenomenon arises apparently from the inductive action of conductors upon one another. Increasing their surface facilitates the discharge by increasing the distance between the mutually opposing forces. This view is confirmed by the following experiment:—

Sixty wires, 2m. long, and 25mm. in diameter, were now placed in parallel. When the wires were 1cm. apart the iron wire was well protected, and did not heat to 400° C.; the closer, however, the 60 wires were brought together, the hotter the iron became; first it got warm, then red hot, and finally, when the wires were in close proximity, melted. When

* Translation of a Paper read by M. C. M. Guillemin before the Académie des Sciences, 14th May, 1866. *Comptes Rendus*, pp. 1,083-85.

Digitized by Google

the wires were twisted into a cable the effect was a maximum. By exaggerating the conditions of the experiment, it is easy to see that a conductor of large surface may have a much higher resistance than a round wire, so far as voltaic currents are concerned, and yet be a better conductor of static discharges.

The original phenomenon was this. In the case of two short, thick conductors, the interposition of a thin layer of air in the circuit of one did not greatly affect the relative quantities of electricity sent through them by an instantaneous discharge.

These results naturally lead me to think that it would be advantageous to substitute copper bands, 2 to 3cm. broad and at least 1mm. thick, for the copper wires at present used on our land lines to connect lightning guards to earth. The presumption is that the protection afforded would be far more thorough.

In these experiments the Leyden jars were changed from a Ruhmkorff coil of large size, and 5 or 6 seconds sufficed to highly charge the 6 jars. The great power of this apparatus permitted me to carry out with ease experiments which it would be very difficult to perform with ordinary apparatus. The Reiss thermometer was used in conjunction with these researches.

LETTERS FOR LEARNERS AND UN-PROFESSIONAL READERS.

BY H. D. WILKINSON.

CHAPTER IX.—*Magnetic Fields.*

(Continued from page 247.)

118. *The "Moment" of a Magnet.*—Looking at the expression, just derived, for the "moment of the couple," acting on a magnet when placed in a magnetic field, it will be noticed that the factors "m" and "l" (strength of pole and length between the poles of magnet) are properties belonging to the magnet itself, and, moreover, the moment of the couple exerted on the magnet depends directly upon the product "$m\,l$." For these reasons, the product "$m\,l$" is designated the "*moment of the magnet,*" and is usually denoted by the letter M. Putting this in the above expression, we have the moment of the couple exerted on a magnet of moment M, when placed in a uniform magnetic field H, is

$$H\,M \sin a,$$

where a is the angle between the magnet and the direction of the lines of force of the field. We are here considering the poles of the magnet as situated at its extreme ends. Although this is not strictly the case, the poles being a little nearer together than the distance between the ends, we may practically regard them as being at the ends, and not introduce any appreciable error. Whatever shape the magnet has, its moment is always the strength of one pole (m) multiplied by the distance between the poles (l), irrespective of what length of metal actually exists between the poles. For example, the moment of a semi-circular magnet is the strength of pole multiplied by the distance between the poles, viz., the diameter of the circle of which the magnet forms part. Or if we suppose a split steel ring, such as a piston ring, to be magnetised, the moment is very small, although the ring may be strongly magnetised, because the distance between its poles is very small; and if the magnetic circle be completed by inserting a piece of soft iron in the gap between the poles, there will be a continuous magnetic circuit through the mass of the metal, and the magnetic moment will be reduced to zero, because there no longer exist any free poles.

119. *Two Uniform Magnetic Fields Superposed at Right Angles to Each Other. The Tangent Principle.*—It is of great importance in all measurements of magnetic fields and in the measurement of electric currents by means of galvanometers to comprehend the resultant action on a magnetic needle suspended in a region where two magnetic fields, whose directions are at right angles to one another, are superposed. The following example will be easily understood. Take a bar magnet, N S (Fig. 79), and place it horizontally at right angles to the magnetic meridian.

The magnetic field surrounding it is indicated generally by the dotted lines. It will be observed that where these lines cross the lines of force H of the earth's horizontal field we have within a limited space two magnetic fields superposed at right angles. Considering the line through the centre of the magnet, it will be noticed that near the region of the magnet the lines

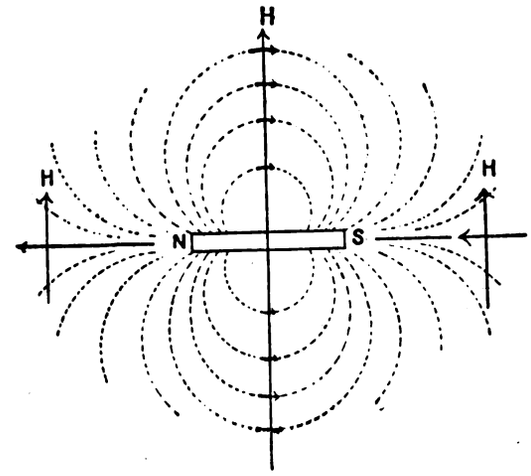


FIG. 79.

of force form small circles, and therefore that portion of a circle which crosses the earth's field H can only be regarded as straight or uniform for a very short length. As we take points further removed from the magnet, however, the circles of force are larger, and that portion of them which cuts H may be taken as straight or uniform for a greater length. At greater distances away from the magnet, however, the intensity of the field becomes lessened.

Now at any given point in this magnetic field there is a *resultant direction* of the lines of force and a *resultant intensity*, which is, in fact, the resultant of the two forces due to the earth and the magnet acting on unit pole at that point. We shall, however, for the present only consider the resultant intensity and direction of the field at points where the two component fields may be considered at right angles to each other. Let us consider a unit pole placed at the point o

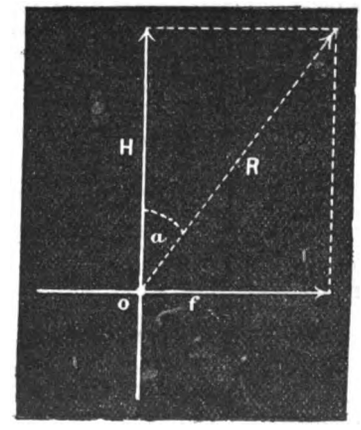

FIG. 80.

(Fig. 80) under the influence of two magnetic fields of H and f units of intensity (para. 109 and 111). Now, these two fields will act on the unit pole with forces equal to H and f dynes (para. 114) in their respective directions, and we may find their resultant in direction and magnitude by the parallelogram of forces. Let the length of the lines H and f be proportional

Digitized by Google

to the respective strengths of the two forces. On completing the parallelogram we get the resultant force R by drawing the diagonal, and if we can determine the angle a, we shall ascertain the *direction* of this resultant. From the parallelogram it is seen that

$$\tan a = \frac{f}{H},$$

and, therefore, the strength of the two fields, or the relation between them, being known, we can determine the direction of the resultant field. This is, in fact, the direction of the lines of force due to the two fields H and f, and a freely suspended magnetic needle will always set itself in the direction of the lines of force of a field when the latter is uniform—that is, when the lines of force are parallel in the region of the needle, which is what we are now considering. If the lines of force are in curves, the needle will set itself as a tangent to the curve. Experimentally, therefore, we may observe this resultant direction by setting up a horizontally-suspended magnetic needle, and first allowing it to come to rest under the influence of one of the fields, say H, the earth's horizontal field, and then bringing into action the superposed field f by placing the magnet N S (Fig. 79) at right angles to the meridian line on which the magnet is suspended. The tangent of the angle moved through by the needle is then equal to the ratio of the two fields, *i.e.*, f : H, and if we know the strength of one of those fields, say that of H, we can find that of the other (f) by

$$f = H \tan a.$$

This is the tangent principle which comes so frequently in use in the measurements of magnetic fields, not only those fields due to permanent magnets, but also electro-magnets, solenoids, and galvanometers. We shall, therefore, refer again to this principle, as proved above, when we have these other magnetic fields under consideration.

Example.—A very short magnetic needle is suspended by a long torsionless silk fibre, so that it is free to move in a horizontal plane. A long light non-magnetic pointer is attached to it, the end of which moves over a scale graduated in degrees, by means of which the angle through which the needle moves may be observed. As soon as the needle has come to rest in the earth's magnetic meridian, a bar magnet is placed at a given distance from the centre of the needle, its position being such that its length is bisected by and is at right angles to the meridian line through the needle. The latter is then observed by the pointer to move through 60 degrees. What is the intensity of the field (f) at the centre of the needle due to the bar magnet?

Answer. $f = H \tan 60$
$= \cdot 18 \times 1 \cdot 7321 = \cdot 31177$ C.-G.-S. units.

Similarly, the intensity of the resultant field may be determined from the same parallelogram (Fig. 80), from which it is evident that

$$\text{resultant field (R)} = \frac{H}{\cos a} = \frac{f}{\sin a},$$

the intensity of which in C.-G.-S. units may, therefore, be found when the strength of one of the fields and the direction of the resultant field, or the angle a of deflection, are known.

Example.—In the last example what is the intensity of the resultant field—

(1) Having given that H = ·18 C.-G.-S. units?

Answer. Intensity $= \frac{H}{\cos 60} = \frac{\cdot 18}{\cdot 5} = \cdot 36$ C. G.-S. units.

(2) Having given that $f = \cdot 31177$ units?

Answer. Intensity $= \frac{f}{\sin 60} = \frac{\cdot 31177}{\cdot 866} = \cdot 36$ C.-G.-S units.

It follows, therefore, that the lines of force surrounding a magnet cannot be symmetrical throughout, since they are really the resultant lines of two fields, that of the magnet and that of the earth. If we only consider the horizontal field of the earth and lay the magnet down horizontally, say at right angles to the meridian, as in Fig. 79, we should not expect to find its magnetic field perfectly symmetrical about its own figure, as drawn in that diagram. When, however, the field is examined by the iron filing method it does appear quite symmetrical, simply because the want of symmetry is only apparent *outside* the area of field made visible by the filings. What the filings reveal to us is really the resultant field, but the earth's field is so weak in comparison to the field in close proximity to the magnet, that the resultant direction is practically that of the magnet's field. It is interesting, however, to detect by a somewhat more delicate means the state of the field from points near the magnet up to distances so far away that the field is no longer apparent. This may be done very well by observing the angles of deflection of a small compass needle placed in succession at various parts of the

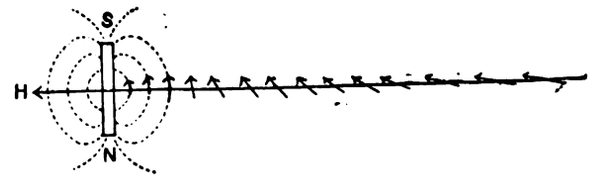

FIG. 81.

field. In Fig. 81 is shown a field so analysed along one direction, viz., the earth's meridian. The small arrows represent the approximate direction of the compass needle when placed at those points, the arrow heads being the needle's north pole, and therefore representing by the direction of the arrows the direction of the lines of force. At a distance from the magnet equal to about six times its length, the needle took up, as nearly as could be observed, the direction of the meridian, showing that the field of the magnet was at this point practically *nil*. The dotted curves close to the magnet N S cover about the area of the field usually indicated by iron filings, the field appearing symmetrical within these limits. A line was drawn on a flat surface corresponding with the magnetic meridian, and divided out into inches. The magnet was then laid down at right angles to the line, being bisected by it. The small compass needle was then placed at each inch mark along the line, and the directions taken up by the needle noted down as nearly as possible as shown in the figure. At the point where the compass needle stood at 45 degrees the two superposed fields were equal, because tan 45° = 1, and therefore $\frac{f}{H} = 1$.

(To be continued.)

THE MAGNETIC QUALITIES OF NICKEL.*

BY J. A. EWING, F.R.S.

The Paper is a supplement to one with the same title by Prof. Ewing and Mr. G. C. Cowan, which was read at a recent meeting of the Royal Society. It describes experiments, conducted under the author's direction, by two of his students, Mr. W. Low and Mr. D. Low, on the effects of longitudinal compression on the magnetic permeability and retentiveness of nickel. The results are exhibited by means of curves, showing the relation which was determined between the intensity of magnetisation of the metal and the magnetising force, when a nickel bar, reduced to approximate endlessness by a massive iron yoke which formed a magnetic connection between its ends, was magnetised under more or less stress of longitudinal compression. Corresponding curves show the relation of residual magnetism to magnetising force for various amounts of stress; and others are drawn to show the relation of magnetic permeability to magnetic induction. Initial values of the permeability, under very feeble magnetising forces, were also determined. The experiments were concluded by an examination of the behaviour of nickel in magnetic fields of great strength. Magnetising forces ranging from 3,000 to 13,000 C.-G.-S. units were applied by placing a short bobbin with a narrow neck made of nickel between the poles of a large electro-magnet, and it was found that these produced a practical constant intensity of magnetisation which is to be accepted as the saturation value.

"THE ELECTRICAL WORLD" IN THE UNITED KINGDOM.

Arrangements have been made by which "The Electrical World" of New York can be obtained from "The Electrician" Office, 1, Salisbury-court, Fleet-street, London, E.C.

The Rate of Subscription (payable in advance), including postage, is £1. 1s. per annum to this Country and Abroad.

Single Copies of "The Electrical World" can also be obtained, price 6d. each.

The Rates for Advertisements in "The Electrical World" of New York can be obtained on application to "The Electrician" Printing and Publishing Company, Limited, as above.

GAULARD AND GIBBS v. FERRANTI.

The decision of Mr. Justice Kekewich by which the patent granted in 1882 to Messrs. Gaulard and Gibbs for "a new system of distributing electricity" has been declared null and void will scarcely surprise anyone who was present in court during the hearing of the case or who may have read even the first portion of the proceedings which we reported last week. At a comparatively early stage it became evident that in the legal aspect of the case, the claim set up on behalf of the patentees for the exclusive right to employ the method of distributing electricity by the inductional transformation of potential rested upon a very slender basis. In order to strengthen their contention for the possession of a wide-sweeping monopoly the patentees had amended their original specification by abandoning the claim which related to a special mode of constructing the transformer. By this means they hoped to show that the specification entitled them to the sole use of any and every system which included the combination of a high-tension alternating-current dynamo with a transformer yielding a lower tension at the secondary terminals, substantially as described. It is, however, solely in virtue of this disclaimer that the patent has now come to grief.

In its original form the third claim for an induction coil of special construction was sufficiently clear and intelligible, even although the details of the construction were not set forth in language of such unmistakable character as to form a model specification. But with the abandonment of this claim the difficulty of determining what is and what is not within the scope of the patent becomes very great indeed. For, notwith-

Digitized by Google

standing the disclaimer, the patentee still retains as part of his combination the *use* of coils of special construction. "He does not," said the learned judge, "claim to construct, but he requires to use certain instruments, and those only when constructed." In other words, Messrs. GAULARD and GIBBS would have been content to allow the whole world to make transformers—even with divided cores and "equal quantities of metal in the two coils"—provided that they alone had the right to use them in combination with an alternate-current dynamo of high tension.

But the amendment of the patent in this particular, apart altogether from the very important question of conformity with the provisional specification, was, said the learned judge, "a very difficult task. I am disposed to think that it could not have been performed without destroying the patent—could not, that is, have been so performed as to leave a supportable residue. But whatever was possible, I hold that it has not been done, and that with the abandonment of the third item of claim the whole specification falls to the ground." The reasons which led the learned judge to this decision were stated in clear and forcible terms. As a condition of being entitled to restrain other operators from producing the required result by the same means, a patentee is bound to disclose in his specification precisely what it is which the public cannot do except under penalty of an injunction; and in the case where the patent rests upon a combination of previously known parts it may reasonably be held that this obligation becomes all the more imperative. Now, taking the specification in its amended form with the disclaimer of the special mode of constructing the coils, a manufacturer might fairly gather that he was still debarred from the user of coils constructed as described; but he might well be in doubt as to whether or not he was entitled to employ in this manner an induction coil whose construction differed in detail from that of the patentees. On behalf of the patentees it was maintained that the use of the divided iron core constituted the special features of the patent. It was not denied that this was in itself an old and well-known construction, but its "combination" with the other features of the system was relied on. Now to make this contention valid it would have to be shown that the specification explicitly referred to the use of this species of transformer *as a class;* but no such reference is made, and all we have is the detailed description of two coils in which divided cores are employed. Similarly, it was urged that the special construction to be used in combination referred also to the "step-down" arrangement—that is, to the diminution of the potential at the terminals of the secondary compared with that of the primary. But it was not pretended that the specification said in so many words that coils of this class were to be employed, and the learned judge held that "nothing less than this would suffice" to maintain the validity of the patent.

It will thus be seen that the patent has succumbed in virtue of its own inherent weakness, and not to the superior claims of any one of its opponents. But although the learned judge abstained from pronouncing a deliberate opinion upon the merits of the patents in which Messrs. GAULARD and GIBBS' device is alleged to have been anticipated, he nevertheless made some remarks which show pretty clearly the view which the Court would probably have taken if it had become necessary to enter upon this side of the case. Mr. ASTON, on the part of the patentees, relied a good deal upon a judgment of Lord WESTBURY'S, in which a clear distinction is drawn between "paper anticipation" and anticipation by manufacture or use. Upon this the learned judge remarked that it became a question whether the various documents which had been referred to did not separately or together add so much to the stock of common knowledge that nothing remained for invention within the limits of Messrs. GAULARD and GIBBS' specification. "As at present advised," said his lordship, "I fail to see how Messrs. GAULARD and GIBBS made any discovery in the technical sense of the word." We do not construe this statement as in any way an impeachment of the *bona fides* of the patentees, who, if they were ignorant in 1882 of the proposals of JABLOCHKOFF, HARRISON, DE MERITENS, and the rest, were only in the same position as Sir WILLIAM THOMSON himself. But we believe that his lordship's view will be endorsed by the majority of our readers who have made themselves acquainted with the facts. For our own part we have always held that Messrs. GAULARD and GIBBS are entitled not only to admiration but also to the gratitude of the electrical world for the plucky way in which they have insisted upon the commercial possibilities of this method of distribution. In the early development of the system they had to face the marked incredulity of the great majority of "practical men," and it is with some satisfaction that we remember that this journal did not take part in the attacks which were repeatedly made upon the efficiency of the system. But our sympathy with the men who fought this battle with ignorance and prejudice cannot lead us to ignore the foresight of earlier labourers whose misfortune it was to be still more markedly in advance of the age. It must also be admitted that the "series" method of working as carried out by Messrs. GAULARD and GIBBS was never a thorough success, and that in the construction of their earlier transformers they showed a conspicuous lack of appreciation of the scientific principles involved. This, however, is but a very mild reproach; and come what may, the names of GAULARD and GIBBS must always occupy an honourable position in the history of the great electrical developments of the nineteenth century.

We may say a word, in conclusion, as to the effect which this decision is likely to have upon the American patent. As our readers are probably aware, the Gaulard-Gibbs patents in America are in the hands of the Westinghouse Company. According to the United States law, a patent in that country expires whenever the same patent terminates in any other country in the world. By the operation of this—as it seems to us—unreasonable law, it will be remembered, a number of EDISON'S patents have recently met with a premature decease. We believe, however, that in the present case the annulment of the English patent will not necessarily involve the United States patent in the same untoward fate. The American specification was drawn up expressly in view of the somewhat uncertain tenure of the English patent, and its claims have been made to rest upon an entirely different footing; so that, as far as the present action is concerned, the Westinghouse Company are probably perfectly secure. The leading claim in the American patent is for the distribution of electricity by means of a (primary) circuit consisting wholly of metal throughout its entire length.

Since the above was written we have received an intimation from Messrs. GAULARD and GIBBS that it is their intention to carry the case to the Court of Appeal.

EFFECTS OF DIFFERENT POSITIVE METALS, &c., UPON THE CHANGES OF POTENTIAL OF VOLTAIC COUPLES.*

BY DR. G. GORE, F.R.S.

In this research numerous measurements were made, and are given in a series of tables, of the effects upon the "minimum point of change of potential of a voltaic couple in distilled water" (Roy. Soc. *Proc.*, June 14, 1888), and upon the "changes of electromotive force attending variation of strength

* Read before the Royal Society, June 21, 1888. Abstract.

Digitized by Google

of its exciting liquid" (*ibid.*), obtained by varying the kind of positive and of negative metal of the couple, and by employing different galvanometers. The measurements were made by the method of balance through a galvanometer, with the aid of a suitable thermo-electric pile (Birmingham Philos. Soc. *Proc.*, Vol. IV., p. 130; *The Electrician*, 1884, Vol. XI., p. 414). The kinds of galvanometer employed were an ordinary astatic one of 100 ohms resistance, and a Thomson's reflecting one of 3,040 ohms resistance.

The following were the proportions of hydrochloric acid (HCl) required to change the potential of different voltaic couples in water :—

TABLE 1.—*Hydrochloric Acid.*

Astatic Galvanometer.

Zn + Pt	between	1 in	9,300,000 and	9,388,185
Cd + Pt	,,	1 ,,	574,000 and	637,000
Mg + Pt	,,	1 ,,	516,666 and	574,000
Al + Pt	,,	1 ,,	12,109 and	15,000

Reflecting Galvanometer.

Zn + Pt	,,	1 ,,	15,500,000 and	23,250,000
Cd + Pt	,,	1 ,,	1,162,500 and	1,550,000
Mg + Pt	,,	1 ,,	775,000 and	930,000
Al + Pt	,,	1 ,,	42,568 and	46,500

With iodine and the astatic galvanometer the following proportions were required :—

TABLE 2.—*Iodine.*

Zn + Pt	between	1 in	3,100,000 and	3,521,970
Mg + Pt	,,	1 ,,	577,711 and	643,153
Cd + Pt	,,	1 ,,	200,431 and	224,637

With bromine and the astatic galvanometer :—

TABLE 3.—*Bromine.*

Mg + Pt	between	1 in	310,000,000 and	344,444,444
Zn + Pt	,,	1 ,,	77,500,000 and	84,545,000
Cd + Pt	,,	1 ,,	3,470,112 and	3,875,000

The magnitudes of the minimum proportions of bromine required to change the potentials of the three couples in water, varied directly as the atomic weights of the three positive metals.

With chlorine the following were the minimum proportions required :—

TABLE 4.—*Chlorine.*

With the Reflecting Galvanometer.

Mg + Pt between 1 in 27,062,000,000 and 32,291,000,000.

With the Astatic Galvanometer.

Mg + Pt	between	1 in	17,000,000.000 and	17,612,000,000
Zn + Pt	,,	1 ,,	1,264,000,000 and	1,300,000,000
Zn + Au	,,	1 ,,	518,587,360 and	550,513,022
Cd + Pt	,,	1 ,,	8,733,585 and	9,270,833
Zn + Cd	,,	1 ,,	55,436 and	76,467

In the case of chlorine, as well as that of bromine, the magnitude of the minimum proportions of substance required to change the potential of magnesium-platinum, zinc-platinum, and cadmium-platinum, varied directly as the atomic weights of the positive metals.

The examples contained in the paper show that the proportion of the same exciting liquid, necessary to disturb the potential of a voltaic couple in water, varied with each different positive or negative metal; and that the more positive or more easily corroded the positive metal, or the more negative and less easily corroded the negative one, the smaller usually was the minimum proportion of dissolved substance necessary to change the potential.

By plotting the results in all cases it was found that the order of change of potential, caused by uniform change of strength of liquid, varied with each positive metal.

The results also show that the degree of sensitiveness of the arrangement for detecting the minimum point of change of potential depends largely upon the kind of galvanometer employed.

As a more sensitive galvanometer enables us to detect a change of potential caused by a much smaller proportion of material, and as the proportion of substance capable of detection is smaller the greater the free chemical energy of each of the uniting bodies (Roy. Soc. *Proc.*, June 14, 1888), it is probable that the electromotive force really begins to change with the very smallest addition of the substance, and might be detected if our means of detection were sufficiently sensitive, or the free chemical energy of the uniting bodies was sufficiently strong.

TEXT OF THE OFFICIAL INSTRUCTIONS FOR THE EXAMINATION OF APPARATUS ISSUED BY THE POSTAL TELEGRAPH DEPARTMENT.

(Concluded from page 278.)

POLE REVERSER.

The two German silver contact-levers must be insulated from the body of the instrument, and the armature lever, in working through the slot must be quite clear of the surrounding metal. The springs attached to these contact levers must be sufficiently flexible to allow the armature to work freely. The instrument should reverse the direction of the current in exactly the same manner as a double current key.

Resistance 40ω

Figure of merit, 83γ (5 large Daniell cells—each of 4ω resistance—without external resistance).

SINGLE CURRENT OR DUPLEX TRANSMITTER.

The stud immediately above the contact spring must be insulated from every other part of the instrument when the armature is at rest. When the armature is attracted it must be insulated from every other part of the instrument. The contact spring must be carefully examined to see that it is not soft. If pressed down by the finger it should be sufficiently flexible to return to its original position and make good contact there.

Resistance 40ω

Figure of merit, 83γ (5 large Daniell cells—each of 4ω resistance—without external resistance).

INKERS.

The ends of the coils must be protected from accidental mechanical injury.

Direct Inker.—The speed of slip should be not less than 6ft. nor more than 7ft. per minute.

Resistance of electro-magnet..... 300ω

,, galvanometer 30ω

Figure of merit: Electro-magnet, 4·9γ (5 Daniell cells through 650ω external resistance). Galvanometer, 10γ (5 Daniell cells through 135ω external resistance), with which the needle should deflect not less than a quarter of an inch, the deflection being to the right hand when copper is connected to the down line terminal.

Differential Coils.—Should be differential (when adjusted for their figure of merit) with 50 Daniell cells without external resistance, care being taken that the current is passed through the coils in both directions.

Resistance of electro-magnet..... 200ω + 200ω

,, ,, galvanometer..... 30ω

Figures of merit: Electro-magnet, 4·9γ (5 Daniell cells through 550ω external resistance). Galvanometer, 10γ (5 Daniell cells through 35ω external resistance), with which the needle should deflect not less than a quarter of an inch, the deflection being to the right hand when copper is connected to the down line terminal.

Local Inker.—The speed of slip should be not less than 6 nor more than 7ft. per minute.

Resistance..... 40ω

Figure of merit, 67γ (5 Daniell cells without external resistance).

AUTOMATIC APPARATUS.

Transmitters.—The speed of slip with old form transmitters should range from not more than 7 to not less than 40ft. (200 words) per minute; and with new form from not more than 7 to not less than 80ft. (400 words) per minute. The thickness of the upper contact arm in the new form single battery transmitter should not exceed 17 mils at the base and 12 mils at the top. The space between the paper roller and the platform should be from 8 to 10 mils wide. The tops of the vertical rods should be flat, and when in their lowest position they should be just level with the upper surface of the platform.

Good signals should be produced on the receiver when a punched slip is passed through either form of transmitter at any speed from the lowest to the highest, the current employed being the figure of merit of the receiver in use. Marking and spacing contacts of equal

Digitized by Google

duration should be made for "reversals." This should be proved by the needle of an induced galvanometer temporarily placed in circuit remaining at zero or moving equal distances on each side of it whilst the instrument is running at any speed. The battery must not be shortcircuited during reversal; nor must it be joined through to the receiving apparatus when the switch is being turned from one position to the other. The connections with the switch in position to receive must be tried by battery and galvanometer.

Receivers.—The printing disc, being dry, should pick up ink promptly when the train is set running at lowest speed. The standard breadth of marks is 16 mils. The standard thickness of Morse paper—an important matter in connection with high-speed apparatus—is 3½ mils. The coils of double-wound receivers should be differential with 50 Daniell cells without external resistance, care being taken that the current is passed through the coils in both directions. A properly adjusted transmitter should be used for the following working tests:—

Receiver, Spring, "For Repeater."—The speed of slip should range from not more than 8 to not less than 36ft. per minute.

Resistance 1,000ω

Figure of merit, for working sounder at key speed, and for printing at 200 words per minute, 3·06γ (50 Daniell cells through 15,000ω external resistance).

Receiver, Spring, old form.—The speed of slip should range from not more than 3 to not less than 36ft. per minute.

Resistance ..... 100ω+100ω

Figures of merit, for working sounder at key speed, the coils being in parallel circuit, and tongues in neutral position, 10γ (20 Daniell cells through 1,800ω external resistance). For printing at 200 words per minute, coils being in series, 17·5γ (20 Daniell cells through 800ω external resistance, a condenser of 2 m.f. capacity being joined across the external resistance).

Receiver, Spring, new form.—The speed of slip should range from not more than 8 to not less than 40ft. per minute.

Resistance ..... 100ω+100ω

Figures of merit, same as for old form spring receiver, but 300 words per minute should be obtained as highest speed.

Receiver, Motor, and Train.—The speed of slip should range from not more than 8 to not less than 60ft. per minute.

Resistance ..... 100ω+100ω

Figures of merit, same as for old form spring receiver, but 400 words per minute should be obtained as highest speed.

Perforator.—Each perforator must be carefully adjusted to the following standard:—If a length of slip be taken containing 121 centre perforations (which number may be obtained without counting by punching the word "telegraph" three times, including the double space between the words), then the distance between the centres of the first and last holes must be exactly one foot. A gauge half an inch wide and nine mils thick should pass freely between the front plates. The standard width of perforator paper is from 460 to 480 mils, and its thickness 4 to 4½ mils.

Rheostats and Resistance Coils

Must be measured coil by coil to see that they agree with the standard set, from which they should not differ more than one per cent. when corrected to the same temperature. Battery testing instruments and Wheatstone bridge coils must not differ more than one-tenth per cent. from the standard set at the same temperature. A letter or letters indicating the description of wire with which the bobbins are wound must be engraved on the ebonite slab of bridge coils, P. being used for platinoid, P.S. for platinum-silver, and G.S. for German silver. (*See* also under Switches.)

Condensers

Must have the capacity of their several sections, and their total capacity, compared with the standard. It should be not more than 5 per cent. above or below the nominal value. The insulation-resistance between the plates must be not less than 300 megohms per microfarad when tested with 400 volts. (*See* also under Switches).

Lightning Protectors.

Plates and bobbins must be tested for insulation. The resistance of the coil of a cable protector must not exceed 4ω. Vacuum tubes must be tested for vacuum by means of the sparks from an induction coil. If the vacuum be good the discharge is blue and glowing; if bad, the spark is white and sharply defined as in air.

Induction Coil for Bottle Battery.

Resistance of primary coil ..... ·1ω
,, secondary coil 160ω

Figure of merit: A spark $\frac{1}{10}$th of an inch long should be obtained when two No. 1 Leclanché cells, parallel, are joined to the primary coil.

Repeaters

Should be joined up with sets of apparatus representing up and down stations, and tried in all ways in which they are required to work. The parts should be tried separately before being mounted on the board.

Electro-Magnetic Switches.—These should be joined up with a single-current key and five Daniell cells, and the armatures should be attracted and remain so when the key is worked in the ordinary way, the adjustment of each armature being such that a piece of Morse paper will just draw freely from between it and the cores when the current is on. Each contact-point should be separately screwed into the levers. Dimensions of adjusting-spirals of ordinary electro-magnetic switch: 32 turns, exclusive of loops, of 14½ mils German-silver wire, outside diameter of spiral $\frac{3}{16}$th of an inch.

Resistance { Electro-magnet..... 60ω / Shunt (copper wire)..... 60ω } 30ω

Relaying sounders "A" are used in some cases as electro-magnetic switches. The resistance of the coils and shunt must be as above.

Indicator Tablet for Repeaters.—These tablets should have the ordinary form of local connections.

Resistance { Indicator, 50ω+50ω, parallel, 25ω / Shunt ..... 2ω } 1·85ω

Figure of merit, 478γ (1 No. 1 Leclanché cell without external resistance), which should release the shutter and close the local circuit through the armature.

Multiplex Apparatus.

Distributor.—Each four corresponding teeth of the driving wheel should meet their respective pole-pieces simultaneously, a difference of $\frac{1}{64}$th of an inch being the largest error allowed. The spaces between the contact segments should be brushed out by means of a tooth-brush, the plate with intervening segments being removed for the purpose before the electrical tests are applied. The connections of the terminals should be proved by pony sounder and five Daniell cells, and the insulation by horizontal galvanometer and 60 Leclanché cells. The arm must be fixed in such a position on the axle that the brush shall rest on the centre of the first segment of one of the sets of receiving correcting segments when a permanent current through the driving coils is holding the wheel stationary. At the end of the tests the mercury box must be carefully examined to see that no leakage has occurred.

Resistance (50ω+50ω, parallel) 25ω

Figure of merit for driving, 400γ (say 30 Daniell cells—three sets of 30 large cells, parallel—through a total resistance of 75ω); the brush being raised so as not to touch the segments.

Reed.—The reed when driven by 5 large Daniell cells, and having the slide-weight midway in its range, should give not less than 5,200 nor more than 5,300 vibrations per minute; the speed being ascertained by the number of dots produced in a quarter of a minute as shown by a Wheatstone receiver, which, with its coils in parallel circuit and having a bias of opposite effect to the current, should be joined up with 5 Daniell cells to the distributor terminals of the reed. A shunt of 500ω should be joined across the driving coils to save the contacts. The slide-weight must be so tight that it will not shake out of position when the reed is working.

Resistance of driving coils 20ω
,, correcting coils { Electro-magnet. 5ω / Shunt ..... 0ω } 3·3ω

Reed Stand.—There must be a space of not less than ¼ of an inch between the top of the ·2 m.f. condenser and the bottom of the base of the reed.

Telephone Apparatus.

Gower-Bell Telephone.—These must be tried with a standard instrument, two No. 1 Leclanché cells being used for speaking.

Resistance of primary coil ..... ·5ω
,, secondary coil 250ω
,, receiver 200ω
,, relay ..... 50ω+50ω

Figure of merit of relay, coils being in series, 6γ (3 No. 1 Leclanché cells through 700ω external resistance).

Bell Telephone:—
Resistance 80ω

Crossley's Transmitter (Microphone, Induction Coil, and Press Button).—These should have the Gower-Bell microphone, and mouthpiece and bend, but the original induction coil.

Resistance of primary coil 1ω
,, secondary coil..... 200ω

Switch-Board Telephone (Microphone and Receiver and Press Button for Short-circuiting Secondary Coil).—Resistance of receiver, between 60 and 100ω.

Each of these instruments, having been provided with the additional parts rquired to make them complete, should be tried in connection with a standard instrument.

Digitized by Google

Switch-Board Telephone Tablet (Reversing Lever, Induction Coil, and a pair of Double-Contact Switch Springs, and Plug).—The connections and insulation of the various parts should be proved by a battery and galvanometer. The lever should go down when a weight of 12 ounces is hung upon it.

Resistance of primary coil ..... ·5ω
,, secondary coil 250ω

Telephone Relays.—The coils should be differential with 50 Daniell cells without external resistance, care being taken that the current is passed through them in both directions : the play and position of the contact-arm being the same as for the figure of merit test, but the tension of the spring being taken off.

Resistance ..... 50ω+50ω

Figure of merit, coils in series, 6γ (5 Daniell cells through 700ω external resistance).

Drop Indicator, Polarised, No. 1—

Resistance 100ω

Figure of merit : 11·5γ (5 Daniell cells through 300ω external resistance), with which the pointer should deflect to the stop on either side, the shutter being held up at the same time. The shutter when down must close the local circuit.

Drop Indicator, Polarised, No. 2—

Resistance 1,000ω

Figure of merit : 3γ (20 Daniell cells through 5,500ω external resistance, with which the pointer should deflect not less than $\frac{5}{16}$ths of an inch to the right hand of zero, the shutter being down. The left hand deflection may be neglected. The shutter should afterwards hold up with a current of the same strength (3γ) in either direction. A current of 10·3γ (20 Daniell cells through 800ω external resistance) should then be passed through the coils in opposite directions alternately, and the pointer should return to within $\frac{1}{16}$th of an inch of zero when the current ceases. The shutter when down must close the local circuit.

Drop Indicator, Non-polarised—

Resistance..... 50ω+50ω

Figure of merit, coils being in series, 11·5γ (5 Daniell cells through 300ω external resistance), which should release the shutter, and close the local circuit through the armature.

Annunciator—

Resistance.....40ω

Figure of merit, 30·3γ (5 Daniell cells throngh 90ω external resistance).

Indicator-Relay, Polarised—

The permanent horse-shoe magnet is intentionally left weak. The polarity of its long upper pole, and that of the bottom of the pointer, should be S. The pointer should be made of steel.

Resistance..... (single wound) 500ω+500ω

Figures of merit, coils being in series : Relay, 1·65γ (10 Daniell cells through 5,000ω external resistance), current entering from right hand. Indicator, 2·46γ (10 Daniell cells through 3,000ω external resistance), with which the pointer should deflect ¼ of an inch on either side of zero ; the deflection being towards the terminal at which the current enters.

Indicator Relay, Non-polarised :—

Resistance..... 50ω+50ω

Figures of merit, coils being in series : Relay, 6γ (5 Daniell cells through 700ω external resistance). Indicator, 4·8γ (5 Daniell cells through 900ω external resistance), with which the pointer should deflect ¼ of an inch on either side of zero, the deflection being towards the terminal at which the current enters.

Drop Indicator Tablets.—The connections and action of each indicator should be proved (*see* respective figures of merit). Tablets for non-polarised indicators, and for not more than nine polarised indicators, should be fitted with the ordinary local connections to each base and insulated contact. Those for more than nine polarised indicators should have the copper strap connecting the bases only ; the small centre screw usually fixing each indicator being left out, and the screw holes being continued through the copper strap and tablet, in line with the centre holes of the indicators.

Indicator Tablets for Repeaters (*see* under Repeaters).

Telephone Switches (*see* also under Switches).—These must be tested for continuity and insulation in their various positions. In hole switches the springs must be clear of the woodwork, and must meet truly. Open springs must be held ⅛th of an inch apart by the stops. Pairs of plugs for switches with closed springs should have their opposite sides connected ; and those for switches with open springs their similar sides. The numbers of plugs to be provided are as under :—

2 hole switch	.....	1 pair
,, intermediate	.....	4 plugs
4 hole switch	.....	2 pairs
6 ,, ,,	.....	3 ,,
9 ,, ,,	.....	4 ,,
12 ,, ,,	.....	6 ,,
16 ,, ,,	.....	8 ,,
20 ,, ,,	.....	10 ,,
25 ,, ,,	.....	12 ,,
50 ,, ,,	.....	13 ,,
100 ,, ,,	.....	25 ,,

Speaking Tablets for Telephone Switches—

The top side of each plug (that having the stop-piece) should be joined to the right hand terminal of each pair. The connections and insulation should be proved by battery and galvanometer.

Press Buttons (Three Forms :—Ordinary ; with Back Stop ; and D.C. Reversing)—

These must make their respective connections properly. In that with back stop the lower contact must be made before the upper is broken. In all cases the button should be free when at rest, and not held against the top of the cover by the spring, which might prevent reliable back contact.

Bells.

Trembler :—

Resistance (single wound) ..... 50ω+50ω

Figure of merit, coils being in series, 13·5γ (3 No. 1 Leclanché cells through 250ω external resistance).

Trembler, large :—

Resistance (single wound 50ω+50ω parallel) 25ω

Figure of merit, 60γ (1 No.1 Leclanché cell without external resistance).

Single Stroke (Trembler Form).—These bells have the contact-spring of the ordinary trembler bell removed from the armature, and a steel banking screw substituted for the contact-screw ; the coils being also joined direct to the inside terminal-plates so that the circuit shall not be broken when the armature is attracted.

Resistance (single wound, 50ω+50ω, parallel)..... 25ω

Figure of merit, 114γ (2 No. 1 Leclanché cells without external resistance).

Single Stroke (with or without key) :

Resistance..... 100ω

Figure of merit, 27γ (5 Daniell cells through 50ω external resistance).

Single Stroke Bell for Pneumatic Tubes (with red and white indicator and with or without press buttons) :—

Resistance 108ω

Figure of merit, 46γ (3 No. 1 Leclanché cells without external resistance).

Block Instruments for Pneumatic Tubes, Single or Double.

The stems of the plungers should be quite free in their slots, and they should also have a small amount of play clear of the springs, so as not to prevent the springs from making back contact. In the double form the front upper spring on either side should break contact before contact between the two lower springs is completed. The pointers should have equal magnetic bias towards each side.

Resistance of indicator	.....	12ω
,, Bell	.....	12ω
,, compensating resistance coil (in special form only)	.....	30ω

Figures of merit.—Indicator : Should be first reversed by 106γ (five Daniell cells without external resistance), and should afterwards reverse with 53γ (one Daniell cell without external resistance). Bell, 53γ (one Daniell cell without external resistance).

Wire Finders.

Should deflect between 40° and 50° when a foot of No. 20 G.P. wire short-circuiting a No. 1 Leclanché cell is placed close to the glass and parallel with the needle at zero.

Numbering Machines.

Each machine must be accompanied by

A piece of india-rubber for replacing the printing pad.
One small spanner.
A small wooden rod for setting the machine to zero.

The machine should be set to zero by first bringing the unit-wheel into such a position that the next depression of the wheel will print the figure "1." This must be done by working the machine in the ordinary manner, as the unit-wheel cannot be shifted round in the same way as the other wheels. The locking lever must be examined to see that it acts properly, and the machine must be

Digitized by Google

thoroughly tested by being set to zero and worked several times perfectly.

PREECE'S BLOCK SIGNALS.

	O.F.		N.F.
Resistance of line coils.....	50ω	...	120ω
,, local coils	10ω	...	50ω
,, locking coils	10ω	...	50ω
,, Annett's coil (if provided).		...	80ω

Switch.—Left hand terminal should be connected, under the base, to the switch handle, the centre terminal to the "on," and the right hand terminal to the "off" side.

Bell Semaphore.—Must work well and promptly with 5 Daniell cells.

ELECTRIC LIGHTING ACT, 1882: BOARD OF TRADE REPORT.

The following report by the Board of Trade respecting the applications to, and proceedings of, the Board under the above-mentioned Act during the past year has just been issued :—

"The following application for a provisional order has been received by the Board of Trade since the date of the last report :—

Name of Company Applying.	Name of District.
South Metropolitan Electric Supply Company (Limited).	The whole or portions of the following parishes and districts :— Parish of St. James, Westminster. ,, St. Martin-in-the-Fields. ,, St. George, Hanover-square ,, Lambeth. The City of London. District of Strand Board of Works. ,, St. Giles ditto. ,, Westminster ditto. With certain extra-parochial places.

Several of the local authorities of districts comprised within the proposed area of supply objected to the grant of the order, and after considering their objections the Board of Trade eventually decided to restrict the order to the parishes of St. James, Westminster, and St. Martin-in-the-Fields, with Waterloo Bridge and a small portion of the Victoria Embankment.

The application for a further extension of time for the deposit of capital in respect of the Fulham District Electric Lighting Order, 1884, referred to in the last report, was not proceeded with.

LICENSES.

The following applications for licenses have been received since the date of the last report :—

Name of Place.	Description of Applicant.
Portions of the City of Liverpool.	Liverpool Electric Supply Company (Limited).
A portion of the Parish of St. Margaret, Westminster.	The Kensington Court Electric Lighting Company (Limited).
The City of Dublin (public purposes only).	The Corporation of Dublin.
The District of the Wimbledon Local Board.	The Wimbledon Local Board.
The Parish of St. James, Westminster.	The St. James and Pall Mall Electric Light Company (Limited).

Of these applications, that relating to Liverpool has been granted by the Board of Trade. The remainder are still under consideration.

The license to the Kensington Court Electric Lighting Company (Limited) referred to in the last report was issued by the Board of Trade on the 11th October, 1887.

(Signed) HENRY G. CALCRAFT."

Board of Trade, 29th June, 1888.

Lightning in an Electric Light Installation.—The necessity for having efficient lightning protectors in electric light installations has been once more made apparent. At Servair, in Nebraska, where there are 600 incandescent lamps run off Westinghouse transformers, seven tranformers were destroyed by lightning on the 7th June last.

GAULARD AND GIBBS v. FERRANTI.

THURSDAY, JULY 5TH.

The first witness called for the defence was

Sir WILLIAM THOMSON, who stated that the induction coil was a very old instrument, and for years before 1882 had been made with wire cores. In 1882 it was known how to regulate the quantity and tension in induced currents. Starting with any current in the primary it was known how to produce practically any tension or quantity in the secondary current, and it was known not only to scientists but to instrument makers. The induction coil as ordinarily constructed in 1878 and 1882 would have efficiently produced a secondary current with a certain loss of energy, which they could measure better now than then. There was a loss by reason of magnetic friction, but the coils of that day worked practically with efficiency. Jablochkoff and others carried out the system of putting several induction coils on the same circuit, and there was nothing novel in so doing in 1882. Du Moncel's description of Jablochkoff's arrangement was a perfectly practicable plan of distributing electricity by induction coils from an alternating-current machine. Alternating-current machines were well-known in Jablochkoff's time, and some makers made both continuous and alternating machines. A continuous current was continuous in point of time and direction, but the alternating-current machines were at that time best known and most used. The machine (produced) was a model in general principle of the "Alliance" and De Meritens machines. The induction coil (produced) was an ordinary coil. The core consisted of a bundle of small wires bound together, and could be slipped into the hollow of the non-metallic bobbin. The four ends of the two coils were visible. Either coil could be used as the primary coil, indifferently, and that was known as far back as 1847 or 1848. Noad, in his lectures, explained how to increase or decrease quantity or tension, and his book had been known for very many years. The machine in court was a fair representation of Jablochkoff's machine, though the lamps were different. (The machine was worked in court, and a lamp made to glow.) With the knowledge of 1878 an electrician could have arranged that machine so as to produce any current in the secondary. There was nothing in Du Moncel's description to restrict the current in the primary. An induction coil, properly constructed, was not restricted to high or low tension in the primary. If it had been wished in 1878 to use the machine produced, and described in Du Moncel, over a large area there was no difficulty in the way of doing so. Du Moncel showed that Jablochkoff understood how to produce lights of different intensities. In Jablochkoff's specification there was a substantial disclosure of this arrangement, and from that specification the electricians of 1877 could have arranged a similar system of distribution. There was nothing there to limit the tension of the primary.

His LORDSHIP: As a matter of fact did any electrician apply this system? They had the secret in their hands.

Mr. MOULTON: Not in England my lord.

His LORDSHIP: Why was it not applied?

Witness replied that there was not a demand at that time for electric lighting. Afterwards large districts were lighted in London with arc lights by different companies. It was about 1880 or 1881 that incandescent lamps came into the market. In following out Jablochkoff's specification a competent electrician would certainly have used a divided core. He had no doubt of that from his knowledge of the trade in induction coils at that time. He had made himself acquainted with Imray's specification, and he believed that any electrician reading that in 1881 could have carried out the invention. If the electricity were taken from a battery, several hundred or thousand cells would be necessary to work up the tension. If a machine were used it would certainly have been an alternating machine, and the current could have been sent a long distance by means of a fine wire and an induction coil. Secondary generators would also have been employed, although they were not called secondary generators. He did not think the system either wasteful or impracticable. It was the best system then, and he was not sure it was not the best system now. He had read the provisional specification of Messrs. Gaulard and Gibbs. In his opinion it did not disclose any novel invention at that date. Many inventors at that time had an idea that they could apply an unlimited number of generators, without taxing the power of the dynamo machine, and that idea he believed was present in the minds of Messrs. Gaulard and Gibbs. It was something akin to perpetual motion. There was nothing novel in the patentees' construction of the induction coil. It was not correct to say, as the patentees did, that the diminution of value suffered by the primary current was the sum of the resistance offered by the induction coil. It made no difference in the action of an alternating current whether it was produced by an alternating machine or any other means; but the usual mode of obtaining an alternating current in 1882 was by an alternating-current machine. The patentees said their secondary generators were to be of "special construction," and they were of special construction in the sense that they consisted of coils with the secondary wire divided. From beginning to end of the provisional or complete specification he could not find any indication that the tension of the secondary current was to be lower than the tension of the primary. The secondary generators did not differ from ordinary induction coils in regard to the tension of the secondary, and there was nothing to make the patentees' induction coil more efficient than the induction coils commonly in use at that day. He did not find anywhere in the specification any suggestion that the generators should be put in parallels between the mains; on the contrary, the suggestion was that they should be arranged in simple series. Again, there was nothing in the directions for making the divided cores which was novel at that time, nor was there anything which limited the character of the secondary generators or of the source of the alternating current. Lake,

Digitized by Google

in his complete specification, described in his letterpress an induction coil which appeared to be perfectly efficient. The drawings seemed to represent induction coils with continuous iron cores, which made it defective. With better cores, which were to be had in the market at that time, Lake would have got a practicable induction coil, and an efficient system of distributing electricity. Edwards and Normandy's publication described also a practicable system of distributing electricity by means of secondary generators.

His LORDSHIP: Would you give the same reason for this system not coming into general use which you gave in regard to Jablochkoff's invention?

Witness replied that he would. Moreover, there were no practicable incandescent lights in those days. There were in his opinion sufficient directions in Messrs. Edwards and Normandy's specification to enable an electrician to carry out the system. The same remark applied to Bright's specification, and in his belief there was nothing in these specifications to restrict the tension either in the secondary or the primary. An electrician would always regulate the tension according to the requirements. Harrison's specification was, too, an intelligible direction for carrying out a system of distributing electricity. Deprez gave the clearest indication of the necessity for using high tension if the electricity was going to a considerable distance. In 1882 the advantage of high tension in respect to sending electric energy to a great distance was well known. He did not find in Gaulard and Gibbs's instruction any intimation with regard to this high tension other than common knowledge. The induction coil described by Messrs. Gaulard and Gibbs was not the best form for their purpose, and there were better forms existing prior to their patent. The method of curing Foucault currents was well known in 1882. The relation of the number of turns in the primary to the number of turns in the secondary was well known to Faraday.

Cross-examined by Mr. ASTON: He could not refer to any publication in which the rule as to the number of turns in the primary and secondary was made known prior to 1882. There was nothing new in Gaulard and Gibbs's provisional specification.

Do you find in the provisional specification of Messrs. Gaulard and Gibbs the following elements combined:—An alternating dynamo, connected with a high-tension main, on which are placed at intervals generators to supply local installations?—Yes; but I do not know what high-tension mains are. No doubt high-tension mains would be used for sending a current fifty kilometres. The intention of the patentees was, no doubt, to have a system that could be worked over long distances, and to supply high-tension mains. I saw the system at work for the first time at the Edgware-road station.

Was that the first time you ever saw a system combining a generator consisting of a high-tension dynamo, a high-tension main, a long circuit and local secondary generators or induction coils?—Yes.

When you saw it working you thought it a very nice thing?—It was very interesting.

And apparently the problem of distributing electricity over fifteen miles for lighting purposes was solved by that arrangement. You saw the incandescent lamps at work?—Yes.

You had yourself given some attention to the problem of distributing electric energy so as to supply local installations over a long circuit?—Yes.

I am sure you were highly gratified at seeing that somebody had to a certain extent solved the problem?—It met some practical requirements, but did not meet all the requirements which seemed to Mr. Swan and myself to be essential.

You, with your great practical knowledge, could have done better?—I do not say that, because neither Mr. Swan nor myself could see a better solution. In 1881 I delivered an address to the British Association at York on the subject of the distribution of electrical energy.

And you told us you proposed to use continuous currents with very high tension?—Yes.

And you told your hearers that to use a high tension sufficient to supply installations on a long circuit, say 50 miles, would be a tension which would be very dangerous if used locally in a house?—Yes.

And you told your hearers that you had been occupied in solving the problem, and that you proposed to do it by means of the Faure secondary batteries?—Yes. The Faure battery was a number of cells constituting a reservoir for the reception and storage of electrical energy.

And your idea was that if you had the electricity going along a long circuit with local installations and high tension you would be able to charge your reservoirs with electrical energy?—Yes.

You were very much pleased with the Faure system of storing electricity, and you thought it had solved the problem?—I thought it might possibly solve it.

Prior to that you had endeavoured to work out in your own mind a system of what you called the "step-down" dynamos?—Yes.

At the time you delivered your speech did you know all the electrical devices contained in these prior specifications?—Yes, but not the combinations.

And combinations may sometimes constitute inventions?—Yes.

Witness, continuing, said he should have known at that time how to construct a secondary generator. At the time of his lecture he proposed a very high tension. Witness did not propose to use an alternating dynamo, but a high-tension direct-current dynamo, or several dynamos in tandem or in series. He knew the system at the Grosvenor Gallery. They had there an alternating dynamo, with high-tension main and secondary generators, and the secondary generators were in parallel, not in series. Witness heard of another system at Colchester, but it did not remain long at work.

At the Paris Exhibition Congress, in 1881, the object was to prove the exact position of the science of electricity and its applications, and to compare the results of researches, was it not?—The practical object was to determine on a unit of measurement.

You sat for forty days?—Yes. None of the gentlemen whom he met there showed witness his system of distributing electricity.

There was another important gathering of eminent electricians, when evidence was taking by the Select Committee on the Electric Lighting Bill. Sir William Siemens' idea was that a quarter mile radius was a convenient area for lighting a town, and that was witness's idea also. That was in 1882. Witness did not believe there was any practical way of solving the problem of electric lighting by induction coils to supply the wants of a town until the parallel arrangement of lamps came into force. In 1882 lamps in parallel arrangement were perfectly well known.

Witness read a report from Prof. Fleeming Jenkin, who in 1884 examined Messrs. Gaulard and Gibbs's apparatus at the request of Sir Geo. Elliott. Dr. Fleeming Jenkin, in his report, said the secondary generators employed by Messrs. Gaulard and Gibbs were likely to be of considerable value in electric lighting by lamps over a considerable distance, and that he was not acquainted with any other system by which this could be done. Prof. Jenkin added that the system was based on sound and well-known principles, and that the secondary generators were excellent and greatly in advance of those previously in use. Witness agreed that the system by which energy from a high-tension main could be produced in houses at a low tension was a valuable arrangement.

His LORDSHIP said he was at a loss to know whether Mr. Aston claimed to use secondary generators of "special construction."

Mr. ASTON: Not specially constructed, but specially selected, my lord.

Witness, continuing, said there were two kinds of secondary generators, those with solid and those with divided cores. The solid core instrument was not practically used in 1882. Messrs. Gaulard and Gibbs's specification therefore described in both cases an induction apparatus with divided cores and separate bobbins capable of being grouped for quantity or tension.

And that type of induction apparatus would answer all purposes in connection with a high-tension main, and an alternating dynamo?—Provided the tension in the secondary was greater or at least equal to the tension of the primary. For household purposes it was perfectly well-known that the secondary circuit must have a comparatively lower tension than the main wire. The use of a solid core would cause a considerable loss of energy by reason of the occurrence of Foucault currents.

In Du Moncel's description of Jablochkoff's patent will you point out to me where you can find any direction to use an alternating-current dynamo supplying a high-tension current to the main?—I do not see the word "high-tension."

To save time I will ask you which of these prior specifications most nearly proposes that system represented by the combined operation of an alternating-dynamo machine sending electricity into an electric main in a state of high tension and supplying local installations with electricity to be utilised by means of induction coils with divided cores?—Several of the prior specifications come absolutely to it.

Does Jablochkoff tell you to use high tension?—He does not name it, but it would be necessary to have a high tension in order to carry out the system.

Is it not true that in Jablochkoff's system the tension in the secondary is enormous?—The tension in the secondary is high.

You are not told in Jablochkoff's specification to be careful to have a high tension in the main?—You must have had a high tension.

Does he say anything about a long circuit—50 kilometres, for instance?—No, so far as I am aware; but he mentions an arrangement for distributing electricity over a large building.

Witness, continuing, said he believed an alternating-current machine was intended to be used in Edwards and Normandy's system.

The Court then adjourned.

FRIDAY, JULY 6TH.

On the reassembling of the Court on Friday,

Sir WILLIAM THOMSON's cross-examination by Mr. ASTON was continued: Harrison's specification proposed to send a current from the primary through one conductor of an induction coil, and to light from the secondary wire of that coil. Harrison used a bad induction coil, but that did not vitiate it as an anticipation of Gaulard and Gibbs's invention.

But none of these prior specifications contained any new principle which you did not know when you delivered your address to the British Association at York?—The whole of them applied the induction coil in a way I had never thought of at all.

In your address at York you advocated a dynamo machine, a long wire, and you had in your mind two methods of obtaining a step-down effect in the local installation?—It never occurred to me to use an induction coil, and it never occurred to me that it would be advisable to use an alternating current.

Therefore you would have had to introduce two elements into your system—an alternating dynamo and the induction coil?—Yes.

Where in the specification do you find the three elements which co-operate in Messrs. Gaulard and Gibbs's patent?—I find induction coils; I find a magneto-electric machine with alternating or reversed currents.

But they are to be rapidly broken first?—It is not rapidly broken.

But on page 4 the inventor says, "to get the full effect out of these coils I use a rapidly broken current to charge them?"—Broken is a bad expression. In a magneto-electric machine there is no break in the circuit. The inventor says, "I prefer as source of electricity a magneto-electric machine with an alternating-current. The current is rapidly stopped and sent back, that is all."

His LORDSHIP: The inventor says, "I want a rapidly broken current, and to get that current I prefer to use a magneto-electric machine with an alternating-current."

Digitized by Google

Mr. ASTON: Well, if that is your lordship's view I will not press it.

Can you mention one of these prior inventions which you would not have had to modify in order to make it a success?—Edwards and Normandy's invention required no modification in order to make it a success.

What do you say in regard to De Meritens' system?—De Meritens requires that something should be taken off. It is perfect with the exception of the iron connector between the two parallel bundles of iron wire.

Is that a matter of opinion?—It is matter of knowledge.

And you would also do away with the character of solidity?—I do not advise a liquefaction of the apparatus (laughter).

I mean in contradistinction to laminated?—I would do away with the iron altogether, or else take it off and put on a laminated connector.

Johnson does not tell you that the instrument on which his appliance is based can be replaced by an alternating-current machine?—Yes, he does. On page 6, from line 20 to the end, he speaks of nothing else but an alternating machine.

I am asking where he says that an alternating-current machine can be used in the place of the Bunsen battery on which he bases his discovery?—He bases his discovery on an experiment with a Bunsen battery, and he leaves it to the electrician to go to the best source for his electricity.

Mr. ASTON: If he has the wit to do so.

Witness, continuing, said that so far as Lake's patent was concerned, he would do away with the solid iron core. He had never seen the invention at work.

Re-examined by Mr. MOULTON: In 1884 Prof. Fleeming Jenkin reported that the secondary generators in Messrs. Gaulard and Gibbs's patent were likely to be of great value in electric lighting. Witness was not aware that at the time Messrs. Gaulard and Gibbs had taken out a special patent for secondary generators. Any competent electrician referring to Messrs. Edwards and Normandy's specification would gather that the currents produced by the magneto machines were alternating currents.

Mr. SEBASTIAN Z. DE FERRANTI, the petitioner, said that from 1885 he had given great attention to the distribution of electricity by induction coils, and had taken out patents. He had read the prior specifications, and had heard Sir Wm. Thomson's evidence. Messrs. Gaulard and Gibbs's specification taught the world nothing that was not contained in the prior specification. He agreed with Sir William Thomson's evidence as to the prior specification. After Jablochkoff's invention, in his opinion, the next real advance in electric lighting was placing secondary generators or induction coils in parallel, and altering all the details to agree with that change.

Cross-examined by Mr. ASTON: It was after you saw what was done at the Grosvenor Gallery that you gave your attention to this system of electric lighting?—No, I had given my attention to it before.

When did you see Messrs. Gaulard and Gibbs's invention first?—At the Grosvenor Gallery in 1884.

Was it not after that you took out your patent?—Yes, in 1885.

I believe the real petitioner is Sir Coutts Lindsay?—I am the actual petitioner, and am most affected.

His LORDSHIP: I do not think we can go into that.

Does the solicitor who represents you represent Sir Coutts Lindsay?—For convenience he does.

Prof. JOHN AMBROSE FLEMING stated that he had made himself master of the prior specification, and, generally speaking, he agreed with what Sir William Thomson had said.

Cross-examined: The law of winding induction coils for the purpose of raising or lowering the tension was well known in 1882. In electric lighting experiments very small changes often made all the difference between failure and success. He had never before 1882 seen the three elements disclosed in Messrs Gaulard and Gibbs's specification in co-operation.

Major-General CHARLES EDMUND WEBBER, said he had a practical as well as a theoretical acquaintance with electricity, and he agreed generally with Sir William Thomson's evidence in chief and in cross-examination.

Mr. MOULTON summing up for the petitioner argued that Messrs. Gaulard and Gibbs's specification was necessarily bad if the patentees had not told the public wherein consisted the "special construction" of the generators which he proposed to use. It was a fatal objection that the patentee who claimed the use of a certain apparatus of special form had never told the public what kind of apparatus was within his claim and what was not. The duties of a patentee were clearly defined. He was bound to tell the public fully how to carry out his invention, and bound to let any person who read the specification know what was within the claim, and he should urge that Dr. Hopkinson's evidence had shown clearly that the public, reading Messrs. Gaulard and Gibbs's specification, would not know that they were to use a high-tension current or what special kind of secondary generator they were to employ. The specification ought to be so clear that a manufacturer who was making these kind of instruments would be able to see at once whether he was infringing the patent. There was nothing whatever in Messrs. Gaulard and Gibbs's description to inform the public what things were essential to the success of the apparatus and what were not. It was evident that the patentee himself did not know, and the manufacturer was left to find out what Messrs. Gaulard and Gibbs themselves did not know. That, he submitted, was entirely against the principles of patent law. It was an objection which was a fatal objection, because the public could not be wiser than the patentee. Moreover, the patentee had not given the general principles of his invention; he had simply taken an instance, and had not even given that instance fully or sufficiently, but had left it without any instructions to vary it under different circumstances, and he maintained that that was not a discovery for which the patent laws allowed a patent. It was not sufficient merely to say, "Take a machine of such and such a size," and not to give any instructions how under different circumstances to vary its dimensions. If the patentee had discovered a principle, and given sufficient directions for getting the good effect which his invention produced, he (Mr. Moulton) would be the last person to say he ought so give every rule for getting the best effect. But the inventor here had discovered no new principle; he had simply given an instance of a machine, and most imperfectly described it, and now he wanted to restrain the public from doing what he had never taught them to do. He was perfectly at a loss to know what his learned friend would have to say as to the claim to use special kinds of generators. In the second instance the patentee did not even say it was necessary to use divided cores.

His LORDSHIP: I think it is implied.

Mr. MOULTON remarked that if that were so the patentee had described two generators, both of them with an ordinary divided core, which every witness had said was the ordinary way of making induction coils in those days. It was impossible under those circumstances to say that the generators were of "special construction." There was only one other thing suggested, and that was that the patent should be supported because when Dr. Hopkinson tested it at Edgware-road he found 87 per cent. of efficiency. That, however, would clearly depend upon the proper adjustment of the number of coils, and of the size of the main that took the electricity. Sir William Thomson carried it even further, and said there was nothing which would make the generators any more efficient than the ordinary induction coils. He was not surprised that Sir William Thomson was struck with this system of distributing electricity when he first saw it. He (Mr. Moulton) had not the slightest doubt that the system was of great use. He believed that the exposé of Du Moncel and the specification of Jablochkoff were publications to the world of a thing of real value, but he did not believe that that publication needed any supplement. Jablochkoff started with an alternating-current which passed through up to fifty of these induction coils, and from each of these he drew the supplies for his lamps. The reason why that system did not come into use was that there was no available lamp, and the result had been that that which was really the pioneer had not survived a large number of formidable rivals which had come up since. He failed to see anything in Messrs. Gaulard and Gibbs's specification which was an enlargement of Jablochkoff's system, or anything which entitled them to a patent. Deprez in his specification told them to take a high-tension alternating-current along the main and turn it into a low-tension current when it got to the end. Messrs. Gaulard and Gibbs never said "turn it into low-tension current," so that Deprez really went a great deal further than any other patentees. To try to prove that there was any invention in taking as the source of their high-tension what the witnesses all said was the most natural source of high-tension in the world seemed to him to be a perfectly hopeless task. The two most striking anticipations by far were Edwards and Normandy's and Johnson and De Meritens'. He was not suggesting any bad faith, but the resemblance which Messrs. Gaulard and Gibbs's patent bore to Edwards and Normandy's specification was exceedingly striking. Johnson's system possessed all the elements of success in 1878, but unfortunately there were no incandescent lamps. Johnson pointed out that all they had to do was to get tension enough, and they could send the current to any desired distance, not only along a public road, but into the houses, and he contended that in that specification they had a publication of all that was valuable in the system. Lake, again, clearly showed a complete publication of the ordinary induction coil with divided cores; but none of these systems were adopted, because they were born into the world before there was any need for them. Messrs. Gaulard and Gibbs were more fortunate. In 1882 those gentlemen, and the people who backed them and found the money, did practically apply this system, and Sir William Thomson said he never saw these things practically applied till he saw them at work at the Edgware-road Station; but a man could not support a patent by showing that he had been fortunate enough to get for the first time people to put money into it in order to show the system. The question whether before 1884 this system was used had nothing to do with the issue. No doubt Messrs. Gaulard and Gibbs were entitled to the advantage of those patents which were really new to the world, but they were not justified in doing what that patent, if it were upheld, would enable them to do—that was prevent the rest of the world, and prevent patentees like Jablochkoff and others using in the very best form that method of electrical distribution which they had so clearly put the world in possession of. The thing which had made this system of distribution take this great stride was this—the system of putting generators one after another, so as to drive the current straight through them, had its defects, but someone discovered that by constructing the generators in a suitable manner and arranging them in parallel a great part of the tension of the main had been got rid of. From that moment the system had taken a most important place in electric lighting; but that was a step which was not in any way attributable to Messrs. Gaulard and Gibbs. Their patent must be judged by what it was—a suggestion in 1882 to use a source of electric supply which was well known, to use secondary generators that had no novelty, and simply to take that which others had shown the world before how to use. Looking at all these considerations he asked his lordship to declare that the patent was not a good patent, and that the petitioner had succeeded.

Mr. ASTON then opened his reply on behalf of Messrs Gaulard and Gibbs, and addressed himself first to the question as to whether they did or did not claim generators of special construction. They did not claim generators of special construction, but they did claim a combination in which generators of an indicated class form one of the elements.

His LORDSHIP: It will take sharper eyes than mine to see the difference.

Mr. ASTON said a generator of special construction was not claimed, but the patentee, in claiming his combination, indicated a class of generator which he used in connection with his high-tension main and his alternating dynamo, and that was a claim which he should be prepared

Digitized by Google

to justify. His case was that not one of these prior specifications disclosed any system or any combination of parts that the patentee ever did work or ever could work without some change. On the authority of Lord Westbury, he should argue that the degree of change was in no way material. If a prior specification did in fact describe a combination, then any subsequent patentee who used that combination could not hold his claim; but if there were half-a-dozen prior specifications, and of those prior specifications number one omitted part "A" of the patentee's combination, number two omitted part "B," and number three omitted part "C," then not one of those three specifications was an anticipation of the combination. Messrs. Gaulard and Gibbs's patent possessed three distinct elements in combination, and any alleged anticipation which was to be relied upon must contain these three elements in that form. Sir William Thomson said, and said truly, that all those prior specifications required respectively something to be done to them to make them successful, but he added that that something was obvious. He (Mr. Aston) submitted that the obviousness of these defects was entirely due to the later state of public knowledge. Messrs. Gaulard and Gibbs's patent consisted of a number of induction coils of a character which the patentees indicated, placed at intervals in such position in relation to the main wire that the induced currents could be utilised for lighting or other purposes. He submitted that that was not pointed out in a single one of the prior specifications. In no single case had they an alternating generator like Messrs. Gaulard and Gibbs's combined with a high-tension main like Messrs. Gaulard and Gibbs's, combined with secondary generators such as were described in Figs. 2 and 3 of Messrs. Gaulard and Gibbs's specification. Witnesses had said, it was true, that Jablochkoff's secondary would not answer, but they added that divided cores were well known, and that anybody would have discovered the defect and put in the exact core. He (Mr. Aston) said they must not do that, and in saying that he relied upon previous decisions which had been given by his lordship, and which had been supported by the Court of Appeal. In not one of the prior specifications did they find the patentee saying "I am going to distribute the electric light by a long main wire, and I will tell you how to do it." They did say they were going to sub-divide the light, but not one put on the front of their specification the clear and intelligible statement, "Now the time has come when we can use lamps upon a long circuit, and I will tell the public how to do it." Messrs. Gaulard and Gibbs clearly described what they were going to do, and all the witnesses said that at the Edgware road Station they saw Gaulard and Gibbs's system at work. They saw an installation with a secondary generator of the class described in Messrs. Gaulard and Gibbs's specification working in connection with a main wire. Dr. Hopkinson tested that system, and he found that the tension in the secondary generator was lower than the tension between the terminals of the primary circuit. When Sir William Thomson saw this system at work at Edgware-road he for the first time knew that an induction coil could be used for the step-down purpose which he had proposed to achieve by the Faure accumulator on the dynamo motor.

The learned counsel had not concluded when the Court rose.

SATURDAY, JULY 7TH.

On the re-assembling of the Court,

Mr. ASTON continued his address on behalf of Messrs. Gaulard and Gibbs. The system which Sir William Thomson saw at work at Edgware-road was quite new to him, and the report which Prof. Jenkin made was one which he endorsed. Sir William Thomson did not know anything of the prior specifications before his visit to the Edgware-road, but now that he had seen those specifications, and brought his skill as an electrician to bear upon them, they told him the same tale. Would they have told that tale if he had had his attention called to them without seeing the apparatus at work at Edgware-road? There was not a single witness who was asked whether, after reading the specification of Jablochkoff, of Imray, of Edwards and Normanby, of De Meritens, they could have constructed an apparatus containing the three elements which were contained in the patent of Messrs. Gaulard and Gibbs, and used in the same way. What would a practical electrician have produced if told to construct a machine from either of those descriptions? His friend said that it was not till 1881 that there were any incandescent lamps suitable for either of these inventions. In November, 1879, and in January, 1880, there came upon the world propositions for a perfect incandescent lamp. Jablochkoff's system was never applicable to incandescent lights put upon a long circuit. He did not use high tension in his main, he did not use an induction apparatus to step down; but used it to step up and increase the intensity of the current. Sir William Thomson said he would take out Jablochkoff's solid core and put in a divided core. It was a small thing to do after seeing the Edgware-road installation, or being told to use an induction coil; but it was nevertheless true that down to 1884 Sir William Thomson had never thought of it. Moreover, it would be contrary in every sense to Lord Westbury's ruling to substitute a divided core for a solid core in Jablochkoff's system. In order to make the specification an anticipation Jablochkoff must tell the public that what he wanted to do was what Messrs. Gaulard and Gibbs had tried to do, and that the means he employed were the means which Messrs. Gaulard and Gibbs employed. Jablochkoff's system differed materially from the patent which was the subject of that action in three respects. They were: Want of proper induction coils, and positive directions to use a wrong one; no reference to a long main circuit wire; no reference to the proper kind of tension to be employed. If Messrs. Gaulard and Gibbs's system had been used to drive dynamos, and they attempted to claim it for electric lighting they would be out of court. That would be simply a new use for an old machine; but in this case there was no old machine, and there never was—until it was exhibited at Edgware-road—that combination of parts which produced a successful distribution of electricity for electric lighting on the Gaulard and Gibbs system. Deprez, his learned friend said, had got the very thing. That was in September, 1881, a year and a-half after the incandescent lamps had been upon the market, and yet the only reason his learned friend could suggest why nothing was heard of the Deprez system was that it was before the time. Why did not Sir Coutts Lindsay adopt the most economical course, and choose the Imray system? Messrs. Gaulard and Gibbs could not have said a word, because that system was not within their claim. What he wished to impress upon the Court was that Messrs. Gaulard and Gibbs used the induction apparatus as a step-down instrument. He did not deny that the Ruhmkorff coil could be used alternatively for that purpose, but in no practical installation had it ever been employed as a step-down producer of high-tension. Imray, it was perfectly clear, had intended to use a Bunsen battery. Sir William Thomson would have put into the invention an instrument which Imray had never described; but that was not a fair reading of the specification. Edwards and Normandy did not even point out the object of their invention. The main objection to Lake was that he had described what Sir William Thomson himself admitted would be a very bad arrangement, namely, the solid cores. Sir William Thomson and all the other witnesses declared that if solid cores had been used, those cores would have declared their inefficiency for the purpose. If Messrs. Gaulard and Gibbs had infringed any of these former patents why had they not been brought to book? There was Jablochkoff, with a large company behind him; why did not he say, "You are infringing my patent?" He was aware that that was not a conclusive argument, but it helped his case that none of these prior patentees were able to point to Fig. 1 in Messrs. Gaulard and Gibbs's specification and say, "That is mine." Harrison's specification would, with a few alterations, he was prepared to admit, come very near that of Messrs. Gaulard and Gibbs, and more particularly if it had contained a secondary generator applicable to a group of lights; but Harrison did not show the means by which his invention could be carried into effect. Read by the light of present knowledge, and with alterations and improvements, some of the prior specifications came very near to that of his clients; but they were bound to take the specifications as they were, and he asked his lordship to hold that his learned friend had failed to prove there was any anticipation of Messrs. Gaulard and Gibbs's patent. The next point he had to address himself to was as to whether he was justified in claiming that the specification described Fig. 1, consisting of the combination which he had referred to over and over again. It would be absurd for him to say that Sir William Thomson did not know how to use an induction coil so as to produce a step-down as well as a step-up effect. He thought he was justified in asking his lordship to hold that the first defining clause, in speaking of generators of "special construction," referred to generators having special characteristics, though they were not new *per se*. in Figs. 2 and 3 they had that class of induction apparatus which would supply a current of lower tension than that in the main wire. Prior to the date of the patent, down to the very latest specification, that of Imray in 1881, the use of the induction coil was to increase tension, and therefore he contended that the patentees were justified in saying that it was a new system which they were going to adopt. He quite admitted the patentees in the beginning of the specification referred in terms to a special construction of a generator, and that they intended, because they thought the generators were new, to claim a "special construction;" and he (Mr. Aston) thought he would be able to justify the claim. First, the generators had divided cores, and, secondly, they had a step-down effect. Messrs. Gaulard and Gibbs solved the problem which had been occupying men's minds from the introduction of the incandescent lamp at the latter end of 1879, and that they had solved it was proved by a number of witnesses to whom he was sure his lordship would give credence. Fairly construed, the specification described a combination; that combination was new, it was sufficiently described, and had never been anticipated. It was urged that the apparatus was not sufficiently described, but an inventor was not bound to give what would be without as well as what would be within his patent.

His LORDSHIP: But he is bound to state so clearly what is within it that a workman may know what is without.

Mr. ASTON said that if the workman departed materially from Figs. 2 and 3 of the patentees' specification he would undoubtedly be without the description.

His LORDSHIP: The patentees do not say "Take step down generators," but merely generators of "special construction."

Mr. ASTON said they must be according to Figs. 2 and 3. Messrs. Gaulard and Gibbs conferred upon the electrical world that benefit which the electrical world was waiting for, and which even Sir William Thomson could not supply. Messrs. Gaulard and Gibbs were not bound to point out the salient features of all the parts of their apparatus, and he ventured to sum up the case as being one where there had been no anticipation, where the invention was very useful and beneficial, and where the specification sufficiently described it. It was perfectly well known at the date of the patent that the generators could be placed in parallel, and if the substitution of the parallel for the series system was a thing which anybody could do, then there could be no objection to the specification on the ground that it did not describe the more useful of the two plans. He believed he had dealt with every point raised on the other side, and he submitted that this was a patent which ought not to be revoked.

The Court then adjourned.

JUDGMENT.

Mr. JUSTICE KEKEWICH, in delivering judgment, after referring, on the question of nonconformity of the complete with the provisional specification, to the observations of Lord Blackburn in Bailey *v.* Robertson ("L.R." 3, App. Cases, 1,055), said that the amendment of the com-

Digitized by Google

plete specification had the effect of substituting the specification in its present form for the original ; but in its amended form it must comply with the provisions of the law, including those as to conformity with the provisional specification, as explained in Bailey *v.* Robertson. The provisional specification in the present case spoke of an "unlimited number of induction coils," whereas the complete specification spoke of "a number" only. Was this an essential difference? His lordship decided this question in the negative. One passage of the provisional specification was as follows :—"When an electric current approaches or recedes from a circuit of solenoidical form, it determines in this latter a current of induction without in any way modifying the value of the primary current." It had been said that the provisional specification depended on the statement "without in any way modifying the value of the primary current," and that this was false and was abandoned in the complete specification. His lordship continued as follows:—That that is false is conceded, and for the present purpose it may be assumed that it is abandoned in the complete specification, but I do not think that that fact is fatal to the patent. It may be important as regards utility and also relevant on the question of novelty, but it does not establish nonconformity between the two documents. The most that can be said is that the provisional specification contains, but the complete one omits, an erroneous statement respecting the patented invention which, if scientifically true, would add greatly to its value. That to my mind is not enough. But it is said that, whereas the provisional specification rests the invention on induction coils of a special construction, the complete specification as amended applies it to induction coils of every character, and this makes the latter different in the sense of being more extensive. This is a formidable objection if true. The foundation of it is the abandonment of the claim for special construction. But the patentee, though he has done this—though he has said, "I do not claim to have any special form of induction coil"—has retained, as part of his combination, the use of those of a special construction. He does not claim to construct, but he requires to use certain instruments, and those only when constructed. What is the effect of this on the complete specification standing alone is another question, but on the question of conformity I hold there is no such difference as is alleged between the two documents. Each asserts the necessity for a secondary generator of a special construction. So far, I have dealt with mere questions of language, so as to enable the Court to read the documents for the above purpose. In further examining the specification (and henceforward I deal with the complete one only) one depends much on evidence. There are still questions of construction to be solved, but evidence is required not only to explain terms of art, but to prove what was known at the date of the patent. I may mention here one objection, out of order, to get rid of it. It has been stated by the patentee (Gibbs) that the invention is not thoroughly successful unless there is an equal mass of metal in the primary and secondary wires, and it is urged that, whether true or not, which is said to be immaterial, this ought to have been in the specification. If true, it might, with advantage, have been stated, but it only comes to this, that what is possible with unequal masses and is more feasible as you approach equality, can only be made a thorough commercial success when that equality is practically attained. I do not think that the omission to make such a statement can defeat the patent. Another objection urged respecting secondary generators was that a divided core is essential, and that this is not stated. It is, without doubt, stated as regards the first, and the evidence has satisfied me that it is sufficiently implied in the language describing the second, and further, that no electrician would stop to inquire whether a solid or divided core is intended. But, putting aside these two objections to the description of secondary generators, and assuming, of course, the soundness of my view that they are of special construction, how does the specification stand as regards the information given for their selection? And, in order to get an answer to this question, first consider what information is reasonably required? A patentee is bound to tell the public in his specification, not only what his invention is, but how practical effect is to be given to it, and if the invention be a machine, how that machine can be manufactured. I have paraphrased the statute. If there are many different ways of effecting the entire object, or any particular part of it, he is not bound to specify them all in detail, but he is bound to give such instances—selections it may be from a class—as will enable a competent workman to know what he ought to use. And he is further bound to refer to these instances, or the class from which they come, in language which leaves no doubt what articles are and what are not applicable to the production of the intended result. This is important for two reasons—first, in return for his monopoly, a patentee is bound to put the public in possession, as far as description can do it, of his invention in principle and detail ; and, secondly, as a condition of being entitled to restrain other operators from producing his result by the same means, he is bound to tell them precisely what they cannot do except under penalty of an injunction with its serious consequences, and thus to indicate what can be done safely. This is not less true where the patent is for a combination than in any other case. Indeed, I am not sure that the obligation ought not, in such a case to be particularly strict. If a man says, "I claim to have protected, as my invention, three things combined which, though separately well known, have not been before used together," it is reasonable and right that he should state exactly what each of those three things is; and if any one of them belongs to a class comprehending several varieties, then also which of the varieties are intended. And this, of course, he can easily do, as, admittedly, the combined items are well known. What is the combination, several times described, with some variation of language, but none of substance? Take it from Mr. Aston's statement to his own witness Dr. Hopkinson. The combined elements are three in number—(1) an alternating dynamo supplying a main wire ; (2) a current in that wire of high tension ; (3) a secondary generator such as is described. The description there mensioned is that of the witness, but of course he could only explain or illustrate, he could not go beyond the specification. In passing, let me observe that I am not satisfied that there are really three elements, but I will not dwell on this. Let it be assumed for the present purpose that there are three items—the alternating dynamo, the high tension, and the secondary generators described in the specification. There is no difficulty about the first or second, but how has the patentee fulfilled his obligations as regards the third? It is conclusively proved by the petitioners, and not denied by the respondents, that there is nothing special about the secondary generators described, that they differ from others of their class only in unessential details, and that any other instrument of the class—induction coils with divided core—would answer the purpose equally well. So completely is this admitted by the respondents that they contest the conclusion that a special construction is intended. No more about that. Is it reasonable to hold that the divided core is the special construction? I think not. It would to my mind be pressing the maxim *ut res valeat* too severely to construe the words "electrical generators of special construction" to mean those belonging to one of two well-known and exhaustive classes, especially when one finds no reference to that class as a whole, but an elaborate description of two particular specimens. If the intention had been to refer to electrical generators having a divided core, that might have been easily done in a single line, and the examples would have been needless and out of place. Then it is urged that the special construction refers to the diminution of tension to those which, receiving an electric current of high tension, pass it on as a current of low tension. It is not pretended that this is said in so many words ; no counsel or witness has ventured to put his finger on an expression which states plainly that the secondary generator employed must be of what is styled the "step-down" character. It is conceded that no other will do, and it may be assumed that no other would be attempted by a competent workman ; but this is because of a well-known scientific fact, and not because of information given by the patentee. There is no occasion to examine the provisional specification on this point or to inquire whether the complete specification in its original form is agreeable to the view now taken of it as amended. I hold that, as amended, it does not say one of the elements of the combination is a step down induction coil. That is what you are to use with an alternating dynamo and a high-tension primary wire, in order to produce the desired result. Nothing less than this would suffice. It is not enough to say, as the patentee does, that the qualify and value of the induced currents depend on the special construction of the electrical generators without giving a plain statement in what the special construction consists. It is not suggested that the examples are exhaustive of the class of machines which would answer its purpose. I think that a manufacturer is placed by this specification in a difficulty. He knows, of course, that he cannot use either of the induction coils described, but if he wishes to use one of the same class, but differing in detail, he cannot ascertain from the specification whether he may safely do so or not. Changing the phrase, the patentee has not in his complete specification ascertained the nature of his invention, and how it is to be performed, in that he has not explained what constitutes the third item in his combination. Mr. Aston says, of course the use of equivalents would be an infringement, but I do not think that doctrine can be called in aid of a patent which professedly rests on a special construction. In its original form the specification claimed the special construction of the secondary generators required to produce the desired result. Apart from any question respecting conformity with the provisional specification, the patent could then have been supported, so far as language was concerned ; but the patentee was driven to abandon this part of the claim and to amend by way of disclaimer. This was a difficult task. I am disposed to think that it could not have been performed without destroying the patent—could not, that is, have been so performed as to leave a supportable residue. But whatever was possible, I hold that it has not been done, and that, with the abandonment of the third item of claim, the whole specification falls to the ground. This holding makes it unnecessary to go into the question of anticipation. The evidence on this point is conflicting, and I have the testimony of men of acknowledged eminence and truthfulness on either side. Besides this there are many documents, and the criticism of them has been long and minute. Before pronouncing a deliberate opinion on the question I should be obliged again to examine those documents by the light of the evidence, which would have to be perused for the purpose, and of the arguments, which would have to be recalled and weighed with regard both to documents and evidence. I do not consider myself called upon to do this ; but it may be convenient for me to state what, subject to such revision as I have just mentioned, is the result of my best attention during the trial. I do not question—nobody could successfully question—the accuracy of Mr. Aston's distinction between anticipation by documents only—what is sometimes called paper anticipation—and that by manufacture or use. It is grounded on common sense and established by the authorities to which he referred and many others. Guides for the application of the distinction are also to be found in those cases, and notably in the judgment of Lord Westbury, which Mr. Aston quoted. But the distinction concedes that there may be a paper anticipation, and the question here seems to be whether the documents which have been referred to did not separately or together add so much to the stock of common knowledge that nothing remained for invention within the limits of Messrs. Gaulard and Gibbs's specification. Mr. Aston observed that about the years 1878-9 there was an avalanche of patents, and he accepted my suggestion that many inventors were buried in it. He did not pursue the analogy further, and perhaps forgot that a congealed mass has a law of motion of its own which after a time again brings to light, capable of recognition, though it cannot revivify, buried limbs. So here science has progressed, and in its progress has again called attention to discoveries of bygone years, long buried and forgotten, and of which Sir William Thomson was in 1881 either ignorant or oblivious. Being brought to light, they are recognised as bearing a striking resemblance to others since called into

Digitized by Google

existence, and there is at least some ground for arguing that there is no substantial difference between the past and present. There is often a genuine and complete answer to an argument of that kind. Why, says the patentee of later date, why was not this old invention put in practice if, as you say, it anticipated mine, which has been proved to have been feasible and useful? It is frequently difficult—it is sometimes impossible—to give a satisfactory reply to such an objection, but I think that Sir William Thomson gave one in this case. He says that at that time, the period of those numerous patents, there was no demand for electric lighting—no encouragement, that is, for inventors to persevere and put their inventions in practice. That would scarcely have sufficed; but he added, in effect, that there was not then known any lamp to which those inventions could be usefully applied, that failing any such lamp they necessarily slumbered, but that, such a lamp having been now discovered, their character and value are apparent. That reply, to my mind, detracts largely from the force of the objection to which I have referred. As at present advised, I fail to see how Messrs. Gaulard and Gibbs made any discovery in the technical sense of the word, or, rather, what they published to the world which was not already disclosed by some one or more of the earlier specifications. As I do not propose to examine any of them in detail I will not mention more than one, which was not, I think, the one mostly relied on by the petitioner, and possibly is not the best example. I refer to the specification of Charles W. Harrison, of March 1, 1879. You cannot, it seems, take his description of the third part of his invention any more than you can take any other of the specifications and therefrom build a complete machine according to Messrs. Gaulard and Gibbs's patent—that is, some ingenuity would be required to supplement the directions given. But are not all the necessary directions given? Do they not all concern well-known tools capable of producing well-known effects, and are they not combined precisely as Messrs. Gaulard and Gibbs combine them? Mr. Aston's answer is that the secondary regenerator was employed to alter the tension, not by diminution, but by increase, not by stepping down, to adopt his favourite expression, but by stepping up. This may be true, but it was common knowledge that an induction coil might be used for alteration in either direction, and the application of it in one way instead of the other cannot be deemed invention. Again, Messrs. Gaulard and Gibbs's patent may have taught the electrical world for the first time that high-tension in the primary wire is essential to successful work—in other words, that they have discovered that the best, if not the only useful, mode of using the dynamo for electric lighting is by the creation of high tension. If so, they are entitled to credit for having first seen what other labourers in the same field have failed to see, but ascertaining the best use of a known tool does not fall within the proper definition of invention. The reasons which have prompted me to dispose of this case at once on the point on which I have come to a definite conclusion, and not further to consider those requiring further consideration if my judgment were to be rested on them, render it also unnecessary to deal with the question of utility, but on that I have formed a definite opinion, and it is better that I should express it. Having regard to the great and rapid advance made in this particular branch of science during the last few years, one would expect an invention of 1882 to have been ere this improved upon, if not superseded, and it is not surprising, nor is it any discredit to Messrs. Gaulard and Gibbs's ingenuity, to hear that arrangements on the parallel system are found to be far more effective than those on the series system adopted by the patentees. The evidence indicated, if it did not prove, that the latter would soon give way, if it has not already given way, to the former. On the other hand, I have sufficient evidence that the series system has been successful—not only tried but used and found to work with at least a large measure of success. If, therefore, I could hold the patent to be good on other ground I certainly should not hold it to be bad on the point of utility. For the reasons which I have given I am of opinion that what Messrs. Gaulard and Gibbs describe in their amended specification as their invention, and for which they claim a monopoly, is not the proper subject matter of a patent, that therefore the patent granted to them ought to be revoked, and I must make an order for revocation as asked by the petitioner. The respondents must pay the costs, to be taxed on the higher scale.

PHYSICAL SOCIETY.

At the meeting of this Society, held on the 23rd ult., the President (Prof. Reinhold) in the chair, Prof. S. P. Thompson read a note on

"Continuous Current Transformers."

The author pointed out that continuous-current transformers are of two types. The first of these is the motor-generator, which in its original form consisted simply of a motor driven by the supply current, mechanically geared with a generator producing the outgoing current, and this gradually developed into a single machine having two sets of armature windings on the same core, each set being furnished with a commutator and collecting brushes; one winding receiving the primary current, while the other produced the secondary current. To effect the transformation the armature may be allowed to rotate between the poles of a field-magnet, or the field-magnet and brushes may be made to rotate in the opposite direction while the armature remains fixed. The other type is the commuting transformer, which may consist of a doubly-wound armature, with commutators and collecting brushes as before; but in this case the polarity of a fixed field-magnet is rotated round the armature, which remains fixed. An external fixed ring of the Gramme or Pacinotti type, provided with a commutator, may be used for the method last given, the current being supplied through a pair of mechanically rotated brushes.

In the case of alternate-current transformers Clerk-Maxwell showed in 1867 that the effect of the mutual induction of the two circuits would be equivalent to adding to the resistance of the secondary circuit an apparent resistance equal to that of the primary multiplied by the square of k, the ratio of transformation of the E.M.F., and diminishing the coefficient of self-induction of the secondary circuit by a quantity equal to the coefficient of induction of the primary circuit multiplied by k^2. Where M is the coefficient of mutual induction, n the number of alternations per second, L_1 the coefficient of self-induction of the primary circuit, R_1 its resistance, Maxwell found that

$$k = \frac{2\pi n M}{\sqrt{4\pi^2 n^2 L_1^2 + R_1^2}}.$$

In a Paper read before the Society last year the author showed that in a well-constructed machine the ratio of transformation k is equal to the ratio of the number of secondary windings to the number of primary windings in the transformer.

The object of the present communication is to show that the mutual induction in the two circuits of continuous-current transformers produces effects of the same kind as in the case of alternate-current transformers.

Consider the case of a motor-generator with a doubly-wound armature rotating between the poles of a field-magnet, the magnetism of which is supposed to remain constant. Let C_1 and C_2 be the number of armature conductors on the primary and secondary circuits respectively. Let r_1 be the resistance of the coils of the primary winding, i_1 the current, and E_1 the induced E.M.F., and let r_2, i_2, E_2 be the corresponding quantities for the coils of the secondary winding. Let N be the number of lines of magnetic force passing through the armature, and let e_1 and e_2 be the potential differences at the terminals of the primary and secondary respectively.

Then we have
$$E_1 = n C_1 N 10^{-8},$$
$$E_2 = n C_2 N 10^{-8}.$$

So that
$$\frac{E_2}{E_1} = \frac{C_2}{C_1} = k,$$

independently of the speed and of the strength of field.

Again,
$$E_1 = e_1 - r_1 i_1$$
$$E_2 = e_2 - r_2 i_2.$$

Therefore,
$$e_2 = k e_1 - r_1 i_2 - k r_1 i_1.$$

The author then assumes that $E_1 i_1$, the work done in unit time by the primary current, is equal to $E_2 i_2$, the work done in unit time on the secondary current. This will be very nearly true in a well-constructed machine. This gives $i_1 = k i_2$, and therefore,

$$e_2 = k e_1 - (r_2 + k^2 r_1) i_2.$$

So that the internal resistance of the secondary circuit undergoes an apparent increase of amount equal to $k^2 r_1$.

If there are equal weights of copper in the primary and secondary windings $k^2 r_1 = r_2$, so that the internal resistance of the secondary circuit is apparently doubled.

The author recalled the well known fact that in an ordinary single-wound dynamo the effect of self-induction is an apparent increase in the resistance of the armature owing to the current in each section being stopped and re-started twice in every revolution.

In the double-wound transformers the effect of mutual induction will clearly tend to counteract the effects of self-induction if commutation occurs simultaneously in both the primary and secondary coils wound on the same portion of the core. In practice this neutralisation can never be made complete, but the almost complete absence of sparking in these machines shows that it must be very nearly realised.

If a continuous-current transformer be supplied with a constant potential difference at the terminals of the primary, it will be self-regulating, and give a constant potential difference at the terminals of the secondary, provided the internal resistance of the secondary winding is small, which affords another analogy with an alternating current-transformer. In the case of commuting transformers, precisely similar relations hold good as for motor-generators, as the mutual actions between the primary and secondary windings will be the same whether the common core be mechanically rotated, or the polarity of the field-magnet be electrically rotated.

Mr. KAPP said that the study of continuous-current transformers had been very much neglected, Prof. S. P. Thompson being the only scientist who had taken up the subject. This was doubtless due to their being more expensive to construct and less economical in use than alternate-current transformers. Transformers with two windings on the same armature had been made practically. Commuting transformers of an imperfect kind had been made by Edison.

Digitized by Google

Motor-generators had the great advantage of not sparking, but on account of the necessity of having both the windings on the same armature the insulation was a matter of great difficulty. The surface was necessarily large, and the risk of contact was great, owing to the interlacing of the windings. There was, therefore, great temptation to leakage, and he would not, for example, attempt to transform down from 2,000 volts to 100 volts. There was also a mechanical strain between the windings, though this strain did not take effect on the shaft. There would thus be as much leakage as in a high-tension dynamo. Commuting transformers have the advantage that as there are only the two sets of brushes to rotate, a higher speed can be used than when the whole armature rotates. He considered that Prof. Thompson's plan would, however, lead to a great deal of sparking, and he thought that the commutators would be melted. This difficulty, however, could be overcome by taking advantage of the discovery of Prof. Galileo Ferraris that a rotation of the magnetic field of exactly the kind required could be produced by means of two coils at right angles carrying alternating currents. Mr. Nikola Tesla, in America, had made a practical machine to do the same thing.

Prof. THOMPSON did not think that the difficulty of insulation would be so serious as Mr. Kapp anticipated. He would not attempt to use a potential difference of 2,000 volts with an ordinary Gramme collector, but with the Brush pattern of commutator he did not think there would be any difficulty.

The Existence of an Undulatory Movement Accompanying the Electric Spark.

In the absence of the author, a Paper "On the Existence of an Undulatory Movement Accompanying the Electric Spark," by ERNEST H. COOK, D.Sc., was taken as read.

When sparks pass between two points placed above a plate on which some powdered substance has been scattered, the particles arrange themselves in circular lines, approximately concentric with the projection of the middle line joining the two points. The proximity of the lines is found to be very nearly constant for the same powder, independent of the intensity of the spark used, or the material of the plate. Different powders give different numbers of lines per inch, and mixtures, numbers between those corresponding to their constituents. A great number of substances have been tried, giving numbers between 40 and 88 per inch. These extreme numbers were obtained for chalk and silica respectively. The author has found no satisfactory hypothesis by which to explain the results. A number of photographs accompany the Paper, showing the character of the figures produced.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *June 30th*, 1888.

A little while ago I took occasion to remark on the many advantages which attended the quick appreciation by the daily press of all electric novelties and developments. This marked attention to electrical matters is, however, not without its inconveniences, a fact of which we have had a striking exemplification during the past week, over in the outskirts of Brooklyn, on a Van Depoele electric road, about four miles long, operated by overhead conductors. On this road there happened to be riding during a thunderstorm a German matron, who, according to the testimony of one of her family friends, had spent the sultry afternoon in cooling herself with copious draughts of lager beer. As she was returning home a severe thunderstorm came up, accompanied by heavy rain. The road was once operated by horses, and as the track is still in execrable condition the trolley now and then jumps the wires, especially after the rain has washed out the support of the sleepers below. Thus it occurred that just after a very heavy peal of thunder one of the hangers overhead broke from the strain on it, and the trolley dropped to the roof of the car with a loud noise. The woman immediately became terribly frightened, and it took her some time to recover to any degree from the scare. As soon as she came to she declared that she had received a shock from the current operating the car, and that it had paralysed her. She was confirmed in her belief by a medical man, who, after diagnosing the case, declared that a ball of electricity had passed into her, and was still there! This really amusing incident has been filling columns of the papers for days, and some of the stories have been of the most ludicrous kind imaginable. Of course, it goes without saying that it was utterly impossible for the woman to have received any shock, but at the same time the publicity given to the incident, and the extraordinary yarns in which it is served up to the public make it somewhat difficult for electric railway men to show that after all theirs is the safest means of locomotion in the world. So far as I am aware, no accident of any kind whatever has happened to any of the millions of passengers on the thirty or forty electric roads now in operation, although I believe that in one case a southern mule was rendered *hors de combat*. However, I suppose that, like all new and good things, electric traction must fight its way against misrepresentation, springing as often from ignorance as from dishonesty.

New York has for some time been familiar with the idea of an underground road operated by electricity. A similar scheme has now been presented to the public in Chicago. There it is proposed to carry the road down a distance of 100 or 150ft. deep, and from a central terminus run tunnels in various directions, connecting the business portion of the city with its residential suburbs. This road it is proposed to light by electricity and operate by electric motor. It would be about 27 miles long, and cost about $27,000,000. The road itself would be reached from the surface by means of large passenger elevators, capable of holding 50 or 100 passengers. The depth to which it is proposed to carry the road may seem unusual and objectionable, but it is pointed out that the stratum at the depth of 100ft. is a desirable one of soft limestone, and that no rights of way would have to be purchased. Such a road would be cool in summer and warm in winter. While the passengers might not enjoy much of a view, the dwellers along its route would be saved the horrible noise and dust and steam which distinguish our much-vaunted elevated roads in New York.

Once more the subject of electrical executions is up for discussion, and it cannot be said that the latest developments are very encouraging. It appears that an application was made to Mr. Edison for advice as to the best manner of carrying out the provisions of the law, and that certain experiments were undertaken at the Orange Laboratory by Mr. Batchelor and Mr. Kennelly, with the object of ascertaining as far as possible what was the effect on animal organisms of a strong shock sharply administered. A dog was utilised as a victim, and was placed in the circuit of an alternating machine, giving a potential somewhere in the neighbourhood of 2,000 volts. The dog did not realise his grave position, but the moment the circuit was closed he fell as dead as a doornail. The actual time of execution was two seconds. A notable incident was the flowing of blood from the ears of the dog; and another feature that struck many of the observers was the extreme difficulty of keeping the dog in attitude to receive the shock. Although the experimenters were as humane as the case allowed, the results were altogether such as to dissuade one from the advocacy of such electrical executions with human beings. At the same time it does not follow that the execution of human beings need be so horrible in its attendant circumstances. Mr. Edison suggested last week that it would be enough to manacle the criminal in handcuffs attached to the respective poles of the dynamo, preferably an alternating machine. Mr. Kennelly was pretty much of the same opinion, believing that it would be rather hard to accomplish the intended results very speedily or effectively with the proposed electrical chair.

The hunt after the dead wires in this city has begun in good earnest, although I think that during this hot weather the Subway Board might have allowed us to bask in their shade for a little longer. The point of attack seems to be the tangle of wires representing old and defunct messenger systems, covering the city from one end to the other. These wires roam in every direction, touching countless housetops, and find their way into hundreds of stores and residences, and the conditions under which they become dangerous to life and property may be conceived. Every now and then a new tenant coming into a house goes up on the roof and finds them cumbering it, and at once throws them into the street, probably

Digitized by Google

across electric light wires running below. Here, again, they become a nuisance, till some one at last twists them around the nearest pole; even there they are capable of great mischief, and the only proper thing to do is to clear them out completely.

An interesting little work on municipal lighting has just been issued by Mr. F. H. Whipple, of Detroit, Mich. Mr. Whipple was employed to look into the subject by a special committee of the Detroit Common Council, appointed to examine and report on the feasibility of owning and operating its own electric lighting plant. Mr. Whipple gathered a large amount of information, which was not only laid before the council, but has now been utilised in the work spoken of. The section which deals with the question of the city owning its own plant embraces a large number of examples in which it has been found economical to adopt that course. Thus at Bay City, Mich., allowing for cost of depreciation, it is reported that the city is running 120 arc lights for $6,870 a year from its own plant, while the cost for running gas lights would be nearly $2,000 more. At Lewiston, Maine, the city is operating a plant of 100 lights by water power, and finds that its lights burning all night cost only 15 cents a piece, all charges included. At Hannibal, Mo., the city operates a plant for commercial as well as for street purposes, and in this way gets 52 lights all night long at a total cost per annum to the city of only $2,063. At Paris, Ill., the city plant has been in operation since September, 1885. At Madison, Ind., according to the report of the city clerk, five square miles are lighted by 81 arc lights on mast arms at street intersections. The lights burn all night and every night of the year. The total cost to the city is $4,500 a year. Previous to the adoption of electricity, gas was used with much poorer results, at a cost of $8,000. In a similar manner might be quoted the testimony of Topeka, Kan.; Champaign, Ill.; Huntington, Ind.; Decatur, Ill.; Aurora, Ill.; Portsmouth, O.; Little Rock, Ark.; Sherman, Tex.; and many other places, all of which are getting the utmost satisfaction out of their plant. Such evidence is very significant, and the enthusiastic way in which the City authorities, none of whom are interested in electrical affairs, speak of their electric lights settles the question as to the superiority of the illuminant. I should think that in many places in England where there is yet little hope of starting a company for general commercial business some of your manufacturers of arc apparatus might at least gain a foothold by inducing the City authorities to buy plant for street lighting. The results here are indisputable, and the number of cities owning plants of their own in this country is destined to grow rapidly. The book, I might add, contains also a number of statistics as to the rates paid by the towns and cities running their electric lights on contract. It also contains a large section on the subject of underground wires, showing what has been attempted or proposed by various cities in this matter.

NOTES FROM BERLIN.

(FROM OUR OWN CORRESPONDENT.)

July 11*th*, 1888.

The Allgemeine Elektricitäts Gesellschaft, which has undertaken the lighting of Unter den Linden and the Pariser Platz, commenced the preliminary work some weeks ago. The lead-covered cables are run underground in narrow channels under the pavement at a depth of 18in. The supports for the lamps are 418m. apart, and consist of handsome tapering wrought-iron tubes. Some of the lamps are suspended across the centre roadway on chains.

At the last meeting of the Association of German Electricians, Dr. Rühlmann, of Chemnitz, read a Paper upon the points which determine the particular system that should be adopted on starting a central station. Taking an ideal circular district of 750mm. radius, with a maximum of 10,000 incandescent lamps, Dr. Rühlmann came to the conclusion that the prime cost and annual working expenses were much the same for the different systems in vogue. In compact districts the three-wire system gave the best results, and for dispersed areas the transformer system was the most advantageous.

Dr. Rühlmann also drew attention to the very different conditions under which central stations were worked in Germany and in America. In the States profit alone was thought of; in Germany the public welfare was paramount, no installation being countenanced which had not sufficient chance of success to justify the granting of way-leaves and the possible dangers to life. On the whole, a continuous-current system was the best, since it allowed the station plant to be fully utilised during the day, supplying motive-power and charging batteries, &c. A good meter was an absolute necessity, and each consumer should be independent of the others. A great point was not to charge more for the light than its superiority over other illuminants warranted. In order to do this and yet make the station pay required very careful working and a correct estimate of the maximum number of lamps which might have at any time to be simultaneously supplied. In England and America this maximum was usually taken at about 65 per cent. of the total number of lamps wired. Diagrams taken from the actual working of the two Berlin central stations gave this maximum as 81 per cent. in December, and 16 per cent. in July. Authentic diagrams showing the fluctuations in demand during the day were difficult to obtain. The one obtained from the Markgrafenstrasse Station, and which was in close accordance with the one from Mr. Crompton's station in London, gave the daily average consumption of current at 15·2 per cent. of the possible maximum. This meant an average daily duration of illumination of 3·6 hours or 1,314 hours per annum. Siemens and Halske estimated this figure at 2·5 hours per day, or × 912 hours per annum; Ganz and Co. estimated it at 800 hours per annum.

NOTES FROM PARIS.

(FROM OUR CORRESPONDENT.)

10*th July*, 1888.

In a few days a part of the city of Montpellier will be exclusively lighted by electricity. Before the end of the year the light will be extended to the remaining streets. The present installation consists of forty 2,000 candle-power Thomson-Houston arc lights and 2,000 incandescent lamps. The new theatre, which is to be lit by 1,400 incandescent lamps, fed by a battery of accumulators, will be opened on the 1st September. The plant is being erected by the Victor Popp Company, under the management of Mr. L. Naze, who has already fitted up the Central Station at Tours.

It is said that two applications relating to the installation of central stations for electric lighting in Paris have recently been handed to the Conseil Municipal, but up to now neither the names of the companies nor the quarter they intend to light have been communicated to the public.

The French representative of the Khotinsky Company, from Rotterdam, has entered into a contract with the Rheims Gas Company for fitting up a small central station of 1,200 incandescent lamps, supplied with Khotinsky accumulators. The dynamos will be driven by gas engines. The plant is to be ready for the 1st September next. It will be the first station erected in France on this system, which is said to give satisfaction at the station which this company has fitted up in Berlin.

The lift which will take passengers from the second platform of the Eiffel Tower up to the top will be worked by electricity; the system has been designed by M. Backman.

I hear a good many rumours about a new accumulator introduced by the Société du Travail Electrique des Métaux (the Rothschild Company). This accumulator, known under the name of its inventor, Laurent Cély, is made with melted chloride of lead, reduced by zinc in a solution of sulphuric acid. The inventor says that metallic lead prepared by this process has a density of only 5, and that the plates may be peroxidised without altering their surface.

The military papers of last week make some extraordinary statements with regard to a new microphonic apparatus invented by a lieutenant of the Territorial Army.

This apparatus, contained in a wooden box, is placed two or three feet deep in the ground on the roads which surround forts or camps, and is connected by wires underground with the interior of the fort or camps. By this means the passage of troops, hostile or friendly, is at once made known. According to the statements published, it is also possible to form a very good idea of the strength and the composition of the approaching force. During the experiments made with this apparatus at the manœuvres of the 17th French Corps d'Armée, it is said that the passage of the infantry, cavalry, or artillery was clearly distinguished. It was even possible to estimate the number of men in each corps so approximately that in a body of 5,000 men the error was only 300.

These results are very encouraging, and as the apparatus is probably nothing more than an ordinary microphone, and is therefore neither costly nor liable to get out of order, it is intended to experiment on a large scale.

At the banquet to be given to the Maires de France on the 14th July on the Champs de Mars the electric light will be employed. The current will be furnished from the works of Messrs. Sauter and Lemonnier, Avenue de Suffren, which is adjacent to the Exhibition.

NOTES FROM BRUSSELS.

(FROM OUR CORRESPONDENT.)

THE ELECTRIC LIGHTING OF THE EXHIBITION.

As I have already informed you, the electric lighting of the Exhibition has been subject to many delays and difficulties. In addition to the questions of general administration there were heartburnings among the contractors, and even now some of them are complaining in the papers of the favours shown by the authorities to certain foreign firms. Moreover, the first trials that took place after the opening of the Exhibition left much to be desired; and it is only within the last fortnight that better results have been attained. The technical staff made a great effort, and their work has at length been crowned with success. The lighting is divided into two distinct portions, the lighting of the building and the lighting of the grounds. The first leaves nothing to be desired, and is a very interesting installation from the point of view of economy of light. The machinery annexe, for instance, which has a superficial area of 15,000 square inches, is quite sufficiently well lighted by 68 10-ampere arc lamps; that is to say, by one arc to every 230 square metres, which is, I think, a most economical result. Another point well worthy of notice is the artistic effect of the arc lights, placed high up in the dome. The gardens are lit by arc lamps placed about 15 metres apart on masts. The installation, taken as a whole, is running well, and gives one a good impression. It is to be hoped that there will now be no further difficulties I will conclude with a query—Why has the committee mingled the sacred with the profane, and in some cases called in gas to the aid of electricity? The technical staff, composed of experts convinced of the value of the electric light, are not responsible for a measure so completely unnecessary in the present state of electrical knowledge.

CORRESPONDENCE.

WORKING ALTERNATORS IN PARALLEL.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As the problem of parallel running of alternate-current dynamos on the same circuit has been for some time the object of discussion at various meetings, as well as the cause of some controversies in the papers, I think it will be of some interest for your readers to learn that the above-mentioned mode of operation is no more a problem, but an industrially-accomplished fact. At the central station in Rome I have run in parallel two alternate-current dynamos of 2,000 volts and 45 amperes each, which are separately driven at 250 revolutions by two 150 horse-power steam engines. Also two other generators for 2,000 volts and 160 amperes each, independently driven by two 600 horse-power compound steam engines at 125 revolutions. Due precautions and some care were sufficient to assure a constant uniform tension and light, no "jumping" or other irregularities taking place. Public and private lights were for whole nights supplied from the dynamos in parallel; this would not have been attempted if parallel running of alternate-current dynamos was still in the experimental state. Parallel running of alternate-current generators driven by belting from a common shaft has been done more than two years ago, and offers no points of special interest.—Yours, &c.,

OTTO T. BLÁTHY.

Rome, July 3, 1888.

[We should be glad if M. Bláthy could give further details as to the way in which the arrangements are carried out.—ED. *E.*]

THE CONDITIONS OF REGULATION IN DYNAMOS FOR CONSTANT POTENTIAL.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. Fricker, in referring to my article on the above subject, expresses his opinion that, due to the meagre dimensions of the field-magnets, the discrepancy with which the article mainly dealt was very much exaggerated.

The machine, of the single-magnet type, with cast-iron magnets, was stated to have a magnet cross section of 62 square inches, and an armature cross section of 22 square inches, the latter giving the *two sides of the core added*, each half having an area of 11 square inches. Mr. Fricker thinks I refer to one-half of the ring only in my article, he taking 44 instead of 22 as the total core section. The misconception is due to my having added both sides to give the section, a practice usual in describing single-magnet machines, in order that the respective inductions may be comparable at a glance. The induction in the armature, instead of being 8,630, as given by your correspondent, is 17,260, or in Kapp's notation 18·7 lines per inch. The ratio of the sections of armature and field cores is 1 : 2·82 instead of 1 : 1·41, a proportion which Mr. Fricker will doubtless acknowledge as suitable for the type of machine described.

I quite agree with Mr. Fricker that self-induction may be rendered innocuous by saturating the armature core, but with the armature so saturated the necessity for extra excitement from the series coils, due to self-induction, is practically negligible. To prove this, one has simply to run the machine with no lead, when it will be found that to produce the same E.M.F. in the armature practically the same excitement is required for full load as for no load. In the machine described no difference in the excitement was noticeable, and though for the sake of scientific accuracy self-induction was mentioned as one of the factors producing the discrepancy its influence as compared with other influences necessitating waste excitement may be neglected. The extra excitement is required simply because a lead has to be given to the brushes.

Mr. Fricker having been misled as to dimensions his criticism necessarily loses much of its force; but in case he may, in common with other readers, consider as anomalous the results obtained, I am able, thanks to the courteous manner in which my friends have tendered the information at their disposal, to compare my results with those obtained by other experimenters.

Drs. J. and E. Hopkinson have probably done more towards establishing a complete theory of the reactions of the armature than have any other workers, and the latter reminds me that the term $\frac{m\lambda}{v\pi}$ * has a greater magnitude in ring than in drum armatures. To compensate this is one of the chief objects of the compound winding, and for perfect regulation in the Manchester machine the number of ampere-turns added by the series coil is speaking generally equal to the number of ampere-turns furnished by the shunt. Mr. Kapp informs me that he generally allows 5 per cent. excess excite-

* "Dynamo-Electric Machinery," by J. Hopkinson, M.A., D.Sc., F.R.S., and E. Hopkinson, M.A., D.Sc., *Phil. Trans.*, Part I., 1886, p. 346. Also reprint in *The Electrician*, Vol. XVIII., p. 64, 1886.

Digitized by Google

ment to compensate the armature reactions. Thus, if v be the difference of potentials required at the dynamo terminals and V the loss in volts due to the dead resistance of the armature and series coils the excitement at full load must be such as would produce on open circuit an E.M.F. of $(v + V + 5)$. In the Phœnix machine the excitement required for full load was such as to produce 111 volts on open circuit, and calling S_2 the series turns actually put on the machine, S_1 being the turns inductively useful, we have the ratio $\frac{S_2}{S_1} = 2{\cdot}16$. The ratio in the Kapp dynamo is about the same. Mr. Swinburne finds the ratio $\frac{S_2}{S_1} = 2$ generally applicable, and a good average value for Gramme-wound machines. In very large machines, however, the value of $\frac{S_2}{S_1}$ may become $= 3$. Mr. R. P. Sellon instances a 9,000-Watt Victoria dynamo in which the ratio reaches the high value of 4·15, and assures me that this is representative of any medium-sized Victoria machine.

The figures here given represent the best dynamo practice, and show that the series turns must be from two to four times those given by Prof. Thompson's amended formula. Whether a knowledge of these values will induce Mr. Fricker to be still more mercifully disposed towards that formula I cannot say, but as regards myself, I confess the figures have had a hardening rather than mollifying influence.—Yours, &c.,

W. B. Esson.

DELANY'S KEY ANTICIPATED.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In your number for the week ending the 29th June you mention as a novelty a key constructed by Mr. Delany for working submarine cables by means of alternate currents of equal duration.

This apparatus was anticipated by a similar key for the same purpose which was invented by Sir Charles Wheatstone or Mr. Stroh and successfully tried between London and Amsterdam 20 years ago.

It was observed in working from that form of Wheatstone's apparatus, which transmitted signals like those from an ordinary reverse-current key, that the signals were more liable to delay and distortion from electrostatic induction than those which resembled the signals from the original form of hand-worked magneto transmitter, in which each dot and dash of the Morse alphabet were produced by two short discharges in opposite directions separated by intervals of time which differed with the length of signal required.

The receiving apparatus was adjusted to remain as deflected by the last discharge.

The contact-maker in the key of Sir C. Wheatstone was controlled by a spring in such a way that after having been tilted in either direction by the motion of the key, it continued to move in the last direction until the contact was broken, and the length of the signal transmitted was determined by a fan geared with the contact-maker, which restrained the speed of motion of the contact-maker as required. Thus on depressing the key a marking current of short duration and upon raising it a spacing current of similar length would be transmitted to line.—Yours, &c.,

F. Higgins.

July 9th, 1888.

MAXWELL'S THEORY OF ELECTRICITY.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In your last issue Prof. Lodge points out that the representation which I gave of Maxwell's theory of the magnetic field in Fig. 17 of my fourth article was not taken from Maxwell's Paper, and as it is similar to one of his own given in the Paper in *Nature* to which I subsequently referred, he assumes that it was taken from it. When writing the Paper I had not the opportunity of referring to Maxwell's original Paper, which I read some ten years ago, and only had before me the summary in his "Electricity and Magnetism," Vol. II., page 427 (2nd edition), and a German abstract. In Maxwell's summary he merely states that he supposes some connecting mechanism between the electric whirls, and points out that its determination necessarily admits of an infinite number of solutions. In the original Paper the special solution assumed is that each electric whirl is surrounded by a number of small connecting particles, or idle wheels, and if I had remembered this I should have drawn attention to the much greater simplicity of Prof. Lodge's representation. I had been accustomed to represent Maxwell's theory to myself by the diagram given in my Paper, which appears to represent the simplest form of connecting mechanism which can be imagined, and, therefore, when I read Prof. Lodge's Papers, the only point which struck me as novel in this particular case was his suggestion that alternate whirls might consist of positive and negative electricity respectively.—Yours, &c.,

G. W. de Tunzelmann.

UNIPOLAR INDUCTION.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I am obliged to Mr. De Tunzelmann for the explanation given. What really misled me was the application of Faraday's law as expressed in italics, paragraph 6, page 203. "Passing through the circuit" does not appear to me to sufficiently define the action of cutting the conductor only once, either on entering or leaving, and "rate of decrease in the number of lines, &c.," would seem to imply a decrease in the number during any given interval of time, as compared with another; whereas we know that in unipolar or symmetrical induction effective E.M.F. may be produced, though the rate remain constant, or, what is the same thing, though the number of lines passing as above through a circuit moving with uniform speed be the same for each revolution.—Yours, &c.,

N. G. Thompson.

4, Queen Victoria-street, July 11th, 1888.

FINSBURY TECHNICAL COLLEGE.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I am anxious to place on record my grateful sentiments towards the Principal of the Finsbury Technical College and those of his staff from whom I received instruction during the last two years.

Being a stranger in a strange land when I entered the college two years ago, I can with pleasurable feelings assert that the unvarying kindness of Dr. Thompson has been of the greatest value to me, inasmuch as it has acted as a stimulus in the pursuit of my studies. It would be invidious to single out any individual name among the gentlemen of the staff whose instruction I enjoyed, for they have, one and all, been most painstaking teachers. I beg them to accept this public acknowledgment of my thanks, with the assurance that none can be more sincere.

I hope, Mr. Editor, you will kindly accord me space for the purpose of giving expression to my feelings; and in anticipation of your compliance I also ask you to receive my thanks.—Yours, &c.,

Herman Koerner.

Finsbury Technical College, Leonard-street, E.C.,
July 9th, 1888.

UNITED TELEPHONE COMPANY v. EQUITABLE TELEPHONE ASSOCIATION (LIMITED).

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Having been under the impression that it was a gross impropriety to express an opinion on the merits of a case *sub judice*, we have hitherto, as far as possible, studiously refrained from dealing in a public manner with the persistent efforts made on behalf of the United Telephone Company to damage our interests in the eyes of the public, as well as of their own shareholders, and to try and intimidate those to whom we have supplied instruments. But as the chairman of the United Telephone Company has not hesitated to make

Digitized by Google

public through his speech on the 3rd inst., as reported in your issue of 6th inst., a legal opinion on the probable result (from his company's point of view) of the action now pending between the United Company and ourselves, we think we need no longer hesitate to say that we have as much confidence in the result being in our favour as the United Company's solicitor professes to have on his side, and that we have the opinion of counsel, if not quite so eminent, at any rate as painstaking as the Attorney-General, that our instruments are not infringements of the United Company's patents. As regards our Association fighting the case out, the solicitor of the United Company may certainly be complimented on his sagacity in this respect.—Yours, &c.,

A. A. C. SWINTON, Director,

The Equitable Telephone Association (Limited.)
75, Queen Victoria-street, London, E.C., July 11th, 1888.

ANOTHER ELECTROPATHIC FRAUD.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Would you kindly give your readers the benefit of your experience with regard to the enclosed advertisement? Would socks of this description have the desired effect?—Yours, &c., MAGNET.

Glasgow, 4th July, 1888.

[The advertisement enclosed by our correspondent relates to some "electric socks," which are guaranteed to cure all the ills that flesh is heir to. We are happy to say that we have never had, and trust that we never shall have, any "experience" of this or any other electro-medical quackery. We have, however, no hesitation in denouncing the thing as a fraud of the customary description.—ED. *E.*]

REVIEWS.

Sur l'Emploi de l'Electricite pour la Transmission du Travail a Distance (On the Use of Electricity for the Transmission of Power to a Distance). By J. BOULANGER, Captain of Engineers. (Paris: Gauthier Villars.) 134 pp.

This is a small work, in three chapters, devoted respectively to "The Theory of the Transmission of Power to a Distance," "The History of Electromotors and of the Transmission of Power," and "An Account of the Experiments carried out by Marcel Deprez at Creil."

The introductory general exposition is clear enough, as far as it goes, but brief and incomplete. The statement that Marcel Deprez was the first to show that for economical transmission of power currents of high E.M.F. and small quantity should be used is unfortunately by no means a new one in French books. M. Deprez was the first to show the practicability of the electrical transmission of power on a large scale, and it is a pity that French writers persist in discounting the merit really due to him on this account by the absurdity of crediting him with the discovery of what is simply an immediate consequence of Ohm's law, in conjunction with Joule's law, of the development of heat in an electric circuit.

The "History of Electromotors" consists, with only one or two exceptions, of a history of French electromotors.

Continuous versus Alternate Currents for Measuring the Resistance of Electrolytes.—In a recent number of *Wiedemann's Annalen* S. Sheldon describes a series of experiments made with solutions of potassium chloride, sodium chloride, potassium sulphate, and magnesium sulphate of nine different degrees of concentration, in order to obtain a comparative test of the advantages of the continuous and alternate-current methods respectively. The author found that both methods gave closely concordant results, and his conclusion is that they are both equally accurate and reliable when properly carried out; but he decides in favour of the alternate-current method on the ground of its greater simplicity and convenience.

LEGAL INTELLIGENCE.

The United Telephone Company v. Tasker Sons and Co.

On Friday week last, in the Chancery Division of the High Court of Justice, before Mr. Justice Kay, Mr. Aston, Q.C., on behalf of the plaintiff company, moved to vary the minutes of an order made by his lordship when granting an injunction in the action on a former occasion. Mr. Aston stated that when before the Court on a former occasion the motion was for an interim injunction to restrain the defendants, Tasker, Sons and Co. from using at Sheffield certain telephones which his lordship held were infringements of the plaintiffs' rights. The ground of defence set up was this, that the defendants bought a lot of instruments, and that when they were worn out they replaced them with others, and in respect of the replaced ones the Court held the defendants were not entitled to use them. The defendants at that time represented to the Court there were 52 of these instruments, and an order was therefore made, on the plaintiffs undertaking to supply telephones to replace those wrongfully used, that the defendants should be restrained from infringing plaintiffs' rights. The plaintiffs were prepared to act upon that undertaking, but it now turned out, according to a correspondence that had taken place, that the defendants gave a wrong number, and required 44 instruments over and above the 52 they previously mentioned. Depending upon the defendants' original statement as to the number, the order had been drawn up in too general terms, and the application to-day was to have the minutes varied to the extent of limiting the number of instruments to 52.

Mr. JUSTICE KAY said the order made appeared to be quite right, and he should certainly not alter it, though he would allow the motion to be taken as one to be relieved from their undertaking. In his order he made no limit; he merely restrained defendants from using any instruments that were a contravention of the plaintiffs' rights.

Mr. ASTON: In that case, if they were using 1,000, we should have to supply that number.

Mr. JUSTICE KAY: Yes, that is my order: but you may treat this as a motion to be relieved from your undertaking, on the ground that there was a misstatement in the number.

Mr. ASTON said that if he went into the evidence he could show that not only was there a difference in the number, but a difference in the class of instrument. The learned counsel then read the correspondence that had taken place between the parties since the injunction was granted, after which

Mr. JUSTICE KAY asked why the defendants should not be allowed the use of the extra 44 instruments until the trial.

Mr. ASTON replied that it was contrary to the principles on which the plaintiffs' firm was being conducted.

Mr. JUSTICE KAY: You have got to consider now the principles on which the business of this Court is conducted.

Mr. ASTON: Quite so; and we now ask to be relieved from the undertaking.

Mr. JUSTICE KAY: If I relieve you from the undertaking I shall discharge the injunction.

Mr. ASTON: That is a very heavy penalty.

Mr. JUSTICE KAY: I am not going to allow you to put a stop to their business by refusing to supply them with your patent articles on the usual terms. All I ask you to do is to supply them on the usual terms till the trial of the action.

Mr. ASTON said the plaintiffs were prepared to give the defendants the 52, but would not have them extend their business; therefore the plaintiffs could not undertake to supply the extra 44.

Mr. JUSTICE KAY: If you ask to be relieved of the undertaking, I must relieve the other side of the injunction.

Mr. ASTON: I must accept your lordship's decision to relieve us of the undertaking.

Mr. JUSTICE KAY, in delivering judgment, said: In this case an order was made upon a motion which came on before me the other day, granting an injunction restraining the defendants, who are in possession of a business of an electric telephone agency, from using in that agency any receivers which were infringements of the plaintiffs' patent. There are questions raised which have to be tried at the trial of the action as to the validity of the patent, and so on. The injunction sought for is to restrain the use in the meantime, and it seemed to me fitting that under all the circumstances the use should be restrained in the meantime, which is an order the Court only makes in exceptional cases. Then it was suggested that the object was really a collateral object, that the plaintiffs were themselves setting up a similar agency in Sheffield, and that the real object of the motion was to destroy the business of the defendants, in order to encourage the plaintiffs' own business in that town. Under those circumstances I suggested to the plaintiffs, as a test of their good faith in the matter, that it would be proper that they should upon the granting of any such injunction enter into an undertaking that they would supply on their usual terms—the minutes are very accurate indeed as to that—that they would supply to the defendants, until judgment in this action or further order, on the usual terms as to costs or otherwise, by way of hire, sale, or loan, or letting at their pleasure, so many instruments as shall be sufficient to supply the telephones now in use, which this order will prevent the defendants from using. It seemed to me under all the circumstances that would have been a very fair order, because it is impossible to see how it can harm the plaintiffs in any way unless it interferes with the rival business which they are setting up, and was one

Digitized by Google

they ought to accede to, and they did accede to. The injunction accordingly went, and the order was made in the largest terms "to restrain the defendants until judgment or further order from making, using, or selling, or otherwise disposing of, any telephones which are an infringement of the plaintiffs' patent in the writ of summons mentioned." It is in the largest possible terms, restraining any kind of infringement, and of course the undertaking applied to every instrument the use of which is at the time thereby restrained Then this contest is raised before me. Well, but we are not going to supply them with instruments to extend their business. Certainly not; it is the instruments *now in use*, the instruments they are now using, and which this injunction would prevent them from using. Upon that I think the order is quite explicit, sufficient to supply the place of the telephones now in use. The order is very carefully worded. There was evidence at that time that there were 52 of these instruments in use which this order would prevent their using. A correspondence has now been read which has taken place since this order was made, in which the defendants say they have discovered there are other instruments to which the order would apply. Then they ask them to supply 96—that is the 52 plus 44. Then there is a further correspondence, saying that these instruments were supplied upon a guarantee that they were royalty-paid instruments, but since that the defendants have reason to believe, and have ascertained, that that is not so. I have no evidence before me showing that in the least degree that is an untrue statement. There is nothing to suggest that in making that statement they have discovered since the hearing of the motion there has been any bad faith on the part of the defendants. Now, if the plaintiffs are acting in good faith, I cannot conceive any reason why they should not continue that undertaking. If the purpose of this motion is not to destroy a rival business there is no reason why they should not continue that undertaking. The undertaking as to the 52 was given; that shows there is nothing in the world to prevent their giving it as to the 96. And why the undertaking should not continue as to the 44 extra which the defendants are by that order prevented from using I cannot understand, nor has any reason at the bar been suggested; therefore I come to the conclusion—and it is the only conclusion to which I can come—that this is a device on the part of the plaintiffs to destroy *brevi manu* before the trial of that action a rival business. That I shall not allow. Accordingly, if the plaintiffs now insist upon the right to withdraw from their undertaking it can only be upon the terms that the injunction from this moment is discharged, or that the operation of it is suspended; therefore, I give the plaintiffs the choice. If the plaintiffs choose to withdraw from the undertaking, and not to extend it, not to allow it to include, as in terms it does, these 44 instruments which the defendants now contend are within the same category as to the question of infringement as the 52 mentioned at the hearing of the motion, if they now insist that their undertaking shall not extend to them, then I say the condition upon which this injunction was granted fails, and I refuse to continue the injunction. The matter is entirely for them. I leave it to them. The order which I now make is that if the plaintiffs insist on withdrawing from their undertaking, it can only be on the terms that the injunction is no longer enforced. This motion is brought on quite irregularly—it is a motion to vary the minutes of the order. That motion can only be entertained when the minutes of the order do not correctly express the order the Court made, and there is no ground for saying these minutes do not correctly represent the order the Court made. They are exactly the order the Court made. I am quite satisfied the plaintiffs would be the last persons to be satisfied with the statements that only 52 instruments were an infringement. They sought the injunction in the largest terms, to prevent the infringement of *any*—not of 52—and the injunction was granted, in those terms, to prevent the use of any instruments which were an infringement of the plaintiffs' patent; and it was part of the order that that injunction should only be granted upon their giving that undertaking. Therefore, the motion in the form in which it was was quite irregular; but I have allowed it to be made as a motion to ask the leave of the Court to withdraw from the undertaking that was given, and I grant that leave upon the terms I have stated.

COMPANIES' MEETINGS & REPORTS.

United River Plate Telephone Company.

The second annual ordinary general meeting of this Company was held yesterday (Thursday) at Winchester House, 50, Old Broad-street, under the presidency of the Right Hon. Lord Thurlow.

The SECRETARY (Mr. J. Owen Unwin) read the notice convening the meeting, and the report of the Directors (which was given in our last issue) was taken as read.

The CHAIRMAN: It gives us all very great pleasure to have this opportunity of meeting the body of shareholders again, and it affords us additional gratification to be able to meet you under what I think you must admit to be very satisfactory conditions. You will remember that when we last met neither the Board nor the shareholders themselves could be considered to be quite free from anxiety as to the present or the future. At that time, however, I ventured to express the opinion that the difficulties we were then beset with were of that transient character that might fairly be looked for as one of the necessary and inevitable results of the amalgamation of two hitherto rival companies. Well, gentlemen, I think that what has happened since, happily, has proved the correctness of that forecast, and that, so far at any rate the statements that were made at our last meeting have been fully justified and substantiated. I also expressed at that meeting, if you remember—and I think it was fully shared in by the shareholders—a general feeling of confidence in the ability of Mr. Fels, with the assistance of Mr. Krabbe, to carry us through the difficulties of the amalgamation. That view has also been satisfactorily borne out, and I think you will be glad that I should take this opportunity of bearing some testimony to the ability, the zeal, the energy, and the success which have attended Mr. Fels's administration. You must remember that his position has never been an easy one during these sixteen months, and it is a source of satisfaction to us in these circumstances to reflect that, at any rate, the arrival at Buenos Ayres of the European mails has never added to or tended in any way to increase his anxieties; on the contrary, we never failed to express our confidence in him, and to give him every encouragement in our power and the promise of further assistance if he required it. I think you will all admit that if we had adopted a different course, and had taken any step to restrict his powers at that time, we might have greatly prejudiced your interests. Perhaps I need not say anything more about that, especially as I know that several, if not most of the gentlemen present, and a large body of our shareholders, are intimately acquainted with the difficulties of telephone management generally, and above all of telephone amalgamation. I am bound to say that I think what has been done has been accomplished with a minimum of friction. I do not intend to prophesy or endeavour to forecast at all what may happen in the future, but I will say this much—that I believe that a vigorous and generous policy, such as we have pursued up to the present, of insisting on giving our customers the best service in our power, placing the best instruments in their houses that money will procure, and paying every attention to details, in order to secure the utmost efficiency, will succeed, as it deserves to succeed, in such a business-like community as that we have to deal with in the Argentine Republic. I also think you will agree with me, that while we should exercise, as we have exercised, a due regard to economy in management, still, as occasion may require, it is not our duty to shrink sometimes from what may appear heavy expenditure in order to attain the important result of satisfying our customers. In telephone administration it is true, as it is in most things, that nothing succeeds like success. The greater the number of your subscribers undoubtedly the firmer the hold you have over them, and in my humble opinion it is only by completing the network of that web which we are now spinning in those far-distant lands that we can successfully control and arrive at a position to enable us at all times to defy opposition and any rival schemes. That would be true in any country where the telephone exists; but you must remember that we are dealing with a country where the telephone is an essential part of the daily life of the population, and where the instrument is, as near as may be, exactly ten times as much used as it is in this country. We, therefore, feel sure that it is absolutely necessary to satisfy that large body of the public, and that if you do not succeed in satisfying them to the maximum in a country where no patent rights exist and no exclusive rights can be obtained, undoubtedly opposition and rival schemes will be set forth, and you will have to come to terms. With reference to the development of our business, you were informed before that we have established an exchange at La Plata, we have established a small exchange at Corrientes, and we have entered into a provisional contract for acquiring a very important rival exchange at Rosario. Now, Rosario is no common place; it is remarkable for the energy of its people, for the financial success of all its undertakings, for its rapid increase of population and wealth, and for the general spirit of enterprise which prevails in that city, even to a greater extent than in other parts of that prosperous and go-ahead community of the River Plate. I do not desire to-day to enter into the particulars of that provisional agreement; there are reasons, indeed, why I am unable to do so, but I will say this much, that you may rely upon it that the conditions of that agreement in themselves are of a highly favourable character to the shareholders of this Company. In addition to that it is difficult to exaggerate, in my opinion, the extent to which this purchase will consolidate our position throughout the whole country, will conciliate important interests and increase our hold over the goodwill of the public. It is not necessary for me to trouble you now with any elaborate details as to our large capital expenditure during the past sixteen months. It has undoubtedly been heavy and exceptional, and I shall be happy to reply to any question respecting it as to which I can give an answer without jeopardising any of the interests entrusted to our care. But for the information of the uninitiated it may be interesting that I should state one figure which may appear perhaps somewhat large to those who do not understand the business. I want to say that we have recently erected at Buenos Ayres what is well known to all telephone managers as a multiple switch-board. That multiple switch-board was designed and contrived by some of the most competent experts in the world. It was erected by some of the most competent men sent out to the River Plate for that purpose. It is a very delicate and expensive instrument, and I believe that this newly erected multiple switch-board at Buenos Ayres will favourably compare with anything of the kind that has been erected anywhere. The total cost of that, including erection and other attendant charges, is as near as may be £10,000. Now, comparisons are sometimes useful, and it may be interesting to you to know that so far from that being an unduly high figure, I have recently ascertained that the multiple switch-board erected in New York cost over £50,000. When one is dealing with items of that sort it enables you to form some opinion as to whether our capital expenditure during the last 16 months is very far out of the way or not. I am bound to say, considering what we had to do in connection with the amalgamation of the two systems, that I do not think our capital expenditure can be considered as anything extravagant, though I am free to admit that it is unusual and not at all likely to

Digitized by Google

recur. Of course, with the extension of our system further capital will be required from time to time, but not in the same ratio or to the same extent as during the past sixteen months. As regards our profits and the proposed appropriation of them, I think, considering all things, that the figures representing our trading profits during the last sixteen months cannot be held to be other than satisfactory, especially if you consider that we have had to write off a sum of £10,776 for loss by exchange. Then we have also been able to put a considerable sum to what is practically a reserve, and we have been enabled to do an unusual thing, which is to write off the whole of the preliminary expenses of the formation of the Company, both in England and in Buenos Ayres, during the first sixteen months of our administration, instead of dividing them over a period of years, as is commonly done. Of course, it is unsatisfactory that these figures represent a broken period of sixteen months. In future we hope to be able to render you the accounts in July, which will represent the year's expenditure and profits from March to March. Those dates may be somewhat unusual to select, but in reality we have little choice in the matter ; they suit the fiscal arrangements of the River Plate, and there is no particular inconvenience in our agreeing to them when we have once established that as the date for rendering the accounts. I now come at once to what is always one of the most important, if not the most important, question in the conduct of public companies—I mean the management of the Company and the composition of the Board. You are aware how originally the Board of the Company was selected ; it was supposed to consist of seven members. Three of each of the hitherto rival companies were to be nominated, and those six Directors were to elect an independent Chairman. Those gentlemen did me the very high honour to elect me as their independent Chairman, because I was conversant to a considerable extent with telephones in this country, and because they felt that they could rely upon me at any rate for absolute impartiality if any question should fall to be considered by the Board in connection with the interest of one company or the other. I desire to take this opportunity of stating that as regards the management of the Company and the proceedings at the Board meetings I have absolutely nothing to conceal from the shareholders. Our meetings have been of the most harmonious and friendly character, and though differences of opinion would occasionally prevail where seven gentlemen met to discuss questions of policy, on no occasion have we had to record on our minutes the vote of a minority. I desire to take the opportunity of expressing to my colleagues in your presence my hearty appreciation of the unswerving courtesy that I have met with at their hands. I feel sure also that they would wish me to take this opportunity to express to you, on their part as well as on my own, our high appreciation of the confidence that has been reposed in us by our shareholders in the last sixteen months, and I think it will be found in nine cases out of ten that the prosperity of a company may very fairly be gauged by the extent of the confidence which you find reposed in a Board by the great body of the shareholders. There is one more matter I have to point out. I know there is a feeling abroad, which is shared in by the members of this Board, and has been felt from the commencement, namely, that as opportunities occurred it would be desirable in the selection of new Directors to strengthen what is known as the River Plate element on the Board. That desire has never been absent from our minds. You must remember, however, we have had a Board the bulk of whom have been familiar with River Plate undertakings. We had on our Board, and still have, the father of this enterprise, Mr. Jones, who had intended to be here to-day, but who to his great regret, was obliged to return to America a few days ago. He hopes, however, to be back in two or three weeks, when we shall again have the great advantage of his counsel and advice. Mr. Jones has spent nearly half of the period of sixteen months during which this Company has existed in this country, and it has so happened that very nearly always during his absence we had the advantage of the assistance of another local adviser, Mr. Krabbe, and I find it difficult to express in words the feelings I entertain of the value of Mr. Krabbe's services to this Company.

The Chairman then referred with satisfaction to the provisional election to the Board of Mr. John Coghlan, who was so well known in connection with enterprises in the River Plate. He afterwards expressed regret at the resignation of his seat at the Board by Mr. Bateman, whose services he warmly recognised, expressing also a hope that they would again see that gentleman a member of the Board ; they felt now that there was such a growing responsibility in connection with the large development of their business that they had decided to ask the shareholders to sanction the appointment of two further Directors, increasing the number to nine, although temporarily, it being their intention to reduce that number, as opportunities might occur, certainly to seven again, as at present, and possibly to seven including the local Director at the River Plate. In adopting the report he asked them at the same time to consider that they had sanctioned the appointment of two additional Directors as a temporary measure, and the two gentlemen they proposed to invite to seats at the Board were Mr. George Cooper and Mr. Alfred Le Rossignol. All those who were connected with the affairs of the River Plate would recognise those names as belonging to two of the most able business men that could be selected. He concluded, after expressing his desire to give any further information that might be desired, by moving

"*That the report and accounts submitted to the meeting be and they are hereby received and adopted by the Company, and that the Company declare the dividend recommended in such report.*"

The DEPUTY CHAIRMAN (Mr. J. Irving Courtenay), seconded the motion.

A short discussion followed, in the course of which Mr. Lawrence asked two or three questions respecting the accounts, and Mr. A. H. Baker and Mr. FitzGerald, though satisfied with the report, expressed regret at the resignation of Mr. Bateman from the Board, hoping that he might be induced to reconsider his decision.

The CHAIRMAN, in reply to Mr. Lawrence's question, explained that with regard to sundry creditors the accounts in the balance-sheet represented entries for wages, rent, and other expenses belonging to March, but which were only paid in April. That was a technical point, but it explained a great deal. It also included some subscriptions paid in advance, which also meant a great deal. Subscriptions were very irregularly paid at the River Plate, sometimes being in advance, at other times in arrear. With regard to the sundry debtors, that item represented accounts due to the Company for goods sold, and also outstanding subscriptions ; but the latter, he was happy to say, were much smaller now than they were a few months ago, —speaking roughly, about a half. The cheques would be posted that evening if the dividend was approved. With regard to the remarks of Mr. Baker and Mr. Fitzgerald, he said that the Directors' fees under the Articles of Association were fixed at £1,700 a year. He had fully expressed his views regarding the resignation of Mr. Bateman, whose services he had also expressed his appreciation of, and that some day they would see that gentleman back again on the Board. Nine directors might probably be too many at all times, and therefore he looked upon the increase in the number to which he had alluded as merely temporary. He then put the motion and declared it carried unanimously. Continuing, he proposed the election as Directors of Mr. J. Irving Courtenay and Mr. John Coghlan. Mr. Courtenay had rendered valuable services to the Board, and personally he had derived great assistance from that gentleman being their deputy-chairman, while Mr. Coghlan was well known.

Mr. FITZGERALD seconded the motion, which was carried unanimously.

The auditors, Messrs. Cooper Brothers and Co., were subsequently re-elected.

A cordial vote of thanks to the Chairman, Directors and Officers was then proposed, seconded, and carried unanimously.

The CHAIRMAN having acknowledged the compliment, the proceedings terminated.

The Newfoundland Land Company (Limited).

The fifteenth ordinary general meeting of the shareholders of the above Company was held at Winchester House, Old Broad-street, on Thursday last, under the presidency of Mr. Henry Weaver.

The SECRETARY (Mr. T. H. Wells) read the notice convening the meeting and the minutes of the last ordinary and extraordinary meetings, held on the 5th December, 1887, which were confirmed and signed by the Chairman as correctly entered.

The Directors' report and statement of accounts were taken as read.

The CHAIRMAN formally moved their adoption without comment.

Sir JAMES ANDERSON seconded the resolution, which was carried unanimously.

The auditor, Mr. John Gane, having been subsequently re-appointed,

The Chairman submitted the following report of the committee of shareholders appointed at the extraordinary general meeting of the Company, held at Winchester House, Old Broad-street, E.C., on the 5th December, 1887 :—

TO THE SHAREHOLDERS : It will be remembered that at the above extraordinary general meeting the undersigned were, with the late Mr. George Heiron, appointed a committee for the purpose of selecting a new Board of Directors to undertake the future conduct of the business of the Company.

The committee at the outset desire to express their regret at the loss the Company has sustained by the death of the late Mr. William Abbott, who moved the appointment of the committee, and of Mr. George Heiron, a member of their body, both of whom were prepared to render the new Board of Directors active assistance in conducting the business of the Company. The proceedings of the committee have been much delayed owing to these circumstances.

It appears to the committee that the difficulties which have up to the present resulted in the inactivity of the Company are now being overcome, and the moment appears to be propitious for initiating an energetic policy with reference to land grants. The railway is almost completed, and is at work between the two principal towns of the island, St. John's and Harbour Grace, and extensions are in course of construction to other main points.

The committee would therefore recommend that the attention of the Company should be directed—firstly, to prospecting the lands already allotted, comprising a total of 39,002 acres ; and, secondly, to selecting the balance, being a further 24,999 acres, making a total of 64,000 acres, or 100 square miles.

The object of the Directors should then, in the opinion of your committee, be directed to selling or leasing the land in lots to suit the capabilities and requirements of the fishing population, who also farm on a small scale, and to dispose of such sites as may be suitable for lumber, saw mills, fish-curing warehouses and general industrial establishments, such as are successfully carried out on the opposite coasts of Cape Breton and Nova Scotia, in the Dominion of Canada, fishing, fish-curing and lumber sawing being the staple enterprises of the country.

Your committee are further of opinion that the attention of the Directors might profitably be directed to the examination and testing of the lands of the Company with a view to ascertaining their mineral contents, and, if the exploration of the lands should be sufficiently encouraging, to undertake the necessary exploratory work. Mr. Wingfield

Digitized by Google

Bonnyn, A.M.I.C.E., who has had a long experience and is intimately acquainted with the country, is willing to place his services at the disposal of the Company with a view to the attainment of the foregoing objects, and the committee strongly recommend his appointment.

A small amount of capital will be necessary and sufficient to carry out the foregoing suggestions, and your committee recommend to the Directors the raising of the necessary funds by the issue of debentures not exceeding £10,000, to be issued at a discount of 25 per cent. and carrying interest at the rate of 7½ per cent. per annum.

Your committee have had considerable difficulty in obtaining the consent of gentlemen fitted for the post to undertake the duties of Directors; but they are pleased to be able to report that Mr. Arthur H. Baker, a member of the committee; Mr. Charles Clark, of Messrs. Charles Clark and Co., 20, Great St. Helens, E.C.; and Mr. Henry Wilson, of Maida Vale, N.W., have consented to undertake the position of Directors, at all events for the present. Your committee strongly urge that the Hon. A. M. Mackay, of St. John's, Newfoundland, should be urged to retain his seat at the Board, as, in their opinion, it is essential to the interests of the Company that one or more Directors should be gentlemen resident in Newfoundland.—We are, Gentlemen, yours faithfully,

23rd June, 1888. (Signed) { A. H. Baker. W. Mason Greenip.

The report having been taken as read, Mr. GREENIP formally proposed and Mr. BAKER seconded its adoption.

The CHAIRMAN, in answer to a shareholder, said that the whole of the old Board had resigned in favour of those now proposed, including the Hon. Alexander M. Mackay, of St. John's, Newfoundland.

Mr. DENNY submitted that, though there might be a great future—say 25 years hence—for their property, in view of the present backward state of industries in the district, this was not the time for embarking any more money on it.

Mr. GREENIP could not share Mr. Denny's opinion; what they had to deal with was the present. Either their land was of value or it was not, and if it was of value they could not afford to sit on their stools and wait for its development. They had no option but to take the proceedings suggested to attain the end desired.

In answer to Mr. DENNY the Secretary said that the principal condition on which the land was held was that within five years there should be placed on every 500 acres one settler.

The CHAIRMAN pointed out that the Directors were not at all responsible for the proposed course of action. They were, in fact, of opinion at the time of the last meeting that the Company should be wound up; but the majority of the shareholders did not entertain the same view, and suggested that a more active policy should adopted, so as to make the most they could out of the land. Hence the appointment of the committee and the report now submitted. They could only put the recommendations to the meeting, and abide by the result.

The resolution was unanimously adopted.

It having been previously agreed, on the motion of Mr. GREENIP, seconded by Mr. BAKER, that the Hon. Alexander M. Mackay be requested by the Board to continue as a Director, in view of his local experience and knowledge,

The CHAIRMAN moved and Sir JAMES ANDERSON seconded

"*That Mr. Arthur H. Baker, Mr. Charles Clark, and Mr. Henry Wilson be appointed Directors of the Company, in place of Sir James Anderson, Mr. Henry Weaver, and Mr. William Barber.*"

The resolution having been adopted,

Mr. Cyrus Field's resignation was formally accepted.

Mr. BAKER proposed a vote of thanks to the retiring Directors, paying a warm tribute to their zealous endeavours to make the best of the Company's property in the past.

The CHAIRMAN having briefly returned thanks,

Sir JAMES ANDERSON strongly recommended the shareholders before spending any more money to make themselves acquainted with the facts contained in a number of papers in their hands—the results of some years' experience on the part of the Company's officers of the nature and value of the land and minerals.

The proceedings then terminated.

West African Telegraph Company (Limited).

Directors' report for the year ended December 31, 1887, to be presented at the third ordinary general meeting of the shareholders, to be held at the offices of the Company, 98, Cannon-street, London, E.C., this day (Friday), at 12 o'clock:—

From the balance-sheet and accounts it will be seen that the gross receipts, including the balance brought down from last account (£128. 6s 10d.), amount to £55,268. 4s. 11d., the general expenditure being £21,586. 8s. There remains a balance of £33,681. 16s. 11d., which has been applied by the Directors in the following manner:—After providing for debenture interest paid and accrued, £10,000 has been carried to repairs and renewal account, and it has also been considered advisable to write down the preliminary expenses by £500. These deductions leave an available balance £8,181. 16s. 11d., from which the Directors propose to carry £3,500 to a debenture redemption account, and leave a sum of £4,681. 16s. 11d. to be dealt with, out of which they recommend the payment of a dividend of 3s. per share, free of income-tax, absorbing £3,466. 7s., and leaving £1,215. 9s. 11d. to be carried forward to the current year's account.

The capital account has been increased by the sum of £2,651. 13s. 6d., owing to necessary expenditure in providing proper accommodation for the Company's staff.

The cost of repairing the São Thomé-Loanda section has been taken from the renewal fund, the balance of which is now £1,021. 9s. 6d.

With the exception of the interruption in the São Thomé-Loanda section mentioned in last report, the cables of the Company continued in good working order throughout the year. The Directors are glad to report that since the repair, the Sao-Thomé-Loanda section has given no cause for anxiety, and as the crucial period is passed they venture to hope that repairs off the mouth of the Congo will not be necessary for a considerable time.

The condition of the cables is now perfectly satisfactory, with the exception of the short branch cable from Bulama to Bissao, some 40 miles in length, which was interrupted in April last. As the fault is in shallow water, and the locality well known, it is expected that the defect will be repaired very shortly, and at a comparatively trifling cost.

The Directors have much pleasure in reporting favourably on the manner in which the Company's staff have maintained the service during the past year.

Mr. E. March Webb having been appointed a Director by the Board, the shareholders are asked to confirm the appointment.

Mr. Gray, the retiring Director, being eligible, offers himself for re-election.

The auditors, Messrs. C. F. Kemp, Ford and Co., retire, and offer themselves for re-election.

Notice is given by the Directors that after the completion of the business of the ordinary general meeting an extraordinary general meeting of the Company will be held at the same place for the purpose of considering and, if thought fit, passing, by the requisite majority under the Companies Act, 1862, the following special resolutions, to be confirmed at a subsequent general meeting, of which notice will be given:—

"That the Articles of Association be amended in manner following, that is to say:—

(*a*) Article 81 (as altered by the special resolution passed on the 20th of July, 1887, and confirmed on the 8th of August, 1887) shall be rescinded, and the following Article shall be substituted for it, namely:—

"81. The number and qualification of the Directors may from time to time be altered and fixed by a resolution of a general meeting in accordance with the Company's regulations, but, until otherwise fixed, the minimum number of the Directors shall not be less than three, and the maximum number shall not be more than nine, and no one but a member of the Company who shall hold in his sole name registered shares or stock of the Company of the nominal value of not less than five hundred pounds shall be eligible as a Director."

(*b*) Article 84 shall as from the date of the said special resolution, passed on the 20th of July, 1887, and confirmed on the 8th of August, 1887, be deemed to have been and shall henceforth be rescinded, and the following Article shall as from the date of the said special resolution be deemed to have been and shall henceforth be substituted for it, namely:—

"84. The continuing Directors at any time may act notwithstanding any vacancy in their body, provided always that in case the Directors shall at any time be reduced in number to less than the minimum number for the time being fixed by the Company's regulations or a resolution of a general meeting, it shall be lawful for them to act as Directors for the purpose of filling up vacancies in their body, but not for any other purpose."

Eastern Telegraph Company (Limited).

Report and accounts of the Directors for the half year ended March 31, 1888, to be presented to the thirty-second half-yearly ordinary general meeting, to be held at Winchester House, 50, Old Broad-street, E.C., on Thursday, the 19th inst., at 1 o'clock:—

2. The revenue for the period amounted to £359,706. 0s. 8d., from which are deducted £87,134. 10s. 8d. for the ordinary expenses and £38,412. 5s. 6d. for expenditure relating to repairs, renewals and laying of cables, &c., during the half year. After providing £4,452. 4s. 7d. for income-tax, there remains a balance of £229,706. 19s. 11d., to which is added £29,397. 16s. 5d. brought from the preceding half year, making a total available balance of £259,104. 16s. 4d.

3. From this balance there has been paid:—Interest on Debentures and Debenture stock, £29,835. 14s. 7d.; dividend on Preference shares, £20,384. 13s.; an interim dividend of 1¼ per cent. on the Ordinary shares, £47,500—total, £97,720. 7s. 7d., leaving a balance of £161,384. 8s. 9d., from which £75,000 has been carried to general reserve.

4. The directors now recommend the declaration of a final dividend for the year ended 31st March, 1888, of 2s. 6d. per share and a bonus of 2s. per share, amounting to £85,500, both payable on the 19th inst., making, with the three previous payments on account, a total distribution of 12s. per share, or 6 per cent. for the year on the Ordinary shares. The balance of £884. 8s. 9d. shown at the foot of the revenue account is proposed to be carried forward to the next half year.

5. The revenue includes £34,981. 14s., dividend and interest for the half year upon the Company's investments in the Eastern and South African, the Black Sea, and the Direct Spanish Telegraph Companies. The cables of all these companies are in good working order.

6. The several sections of this Company's cables are in good working order, with the exception of the Aden Bombay duplicate cable, which is interrupted in shallow water about eighteen miles from shore, and will be repaired without delay.

7. With the object of providing a duplicate and alternative telegraphic service to the Cape, the Eastern and South African Telegraph Company (nearly all the shares of which belong to this Company) are making arrangements with the West African Telegraph Company under which the existing line of cables along the West Coast of Africa (now terminating at Loanda) will be continued to Port Nolloth and the Cape of Good Hope.

The new cables will be worked by this Company as part of the Eastern and South African Company's undertaking.

Digitized by Google

The laying of these cables will secure the very important Cape service from the danger of interruption of the existing cables, and provide an alternative line to Aden and India, thus greatly strengthening this Company's position both on the East and West Coast of Africa.

Direct United States Cable Company.

Report of the Directors for the six months ended 30th June, 1888, to be presented at the twenty-second ordinary general meeting of the Company, to be held at Winchester House, 50, Old Broad-street, E.C., on Friday, the 20th inst., at 2 p.m. :—

1. The Directors submit the usual statements of account for the half year ended 30th June, 1888, which, with the half-year's accounts to 31st December last, presented at the ordinary general meeting on the 20th January last, show the financial result of the eleventh year's working of the Company.

2. The half-year's revenue (still subject to revision) including income-tax refunded, and after deducting out-payments, amounted to £17,507. 17s. 2d., against £23,671. 15s. 4d. (after similar deductions) for the corresponding period of 1887, being a difference of £6,063. 18s. 2d. against the half year under review, resulting from the low rates current.

3. The working and other expenses for the same period, including income-tax, but exclusive of cost of repairs of cable, amounted to £15,276. 11s. 10d., leaving a balance of £2,231. 5s. 4d. as the net profit of the half year, making, with £9,910. 14s. 8d. transferred from the reserve fund account, a total of £12,142. For the corresponding half year of 1887 the working expenses and other payments amounted to £15,905 3s. 2d.

4. Three quarterly interim dividends of 2s. each per share, amounting to £18,213, have been declared and paid during the financial year, and a final payment of 2s. per share is now proposed, making, with the three interim dividends, 2 per cent. for the year, being a total distribution of £24.284.

5. Faults having developed in the deep sea portion of the main cable to such an extent as to interfere with efficient working, the Directors, after mature consideration and consultation with eminent telegraph engineers, arrived at the unanimous opinion that the cable should be repaired. They accordingly entered into a contract with the Telegraph Construction and Maintenance Company for the repairs, which have been partially effected, and it is expected that the cable will in a short time be in good working order throughout. The cost of these operations will be dealt with in subsequent accounts.

6. The action brought by the Anglo-American Company against the French Company is still unsettled, the French Company having appealed against the judgment delivered in January last by the Paris Tribunal of Commerce.

7. The 6d. tariff continues. The traffic of the Associated Companies shows a diminution as compared with the last half year.

8. Pursuant to the provisions of the Articles of Association, two of the Directors, viz. :—William Ford, Esq., and C. J. Gunther, Esq., retire by rotation, and being eligible offer themselves for re-election.

9. Mr. John G. Griffiths and Mr. John Sawyer, the auditors, retire pursuant to the Articles of Association, and offer themselves for re-election.

NEW COMPANIES REGISTERED.

WESTMINSTER ELECTRIC LIGHT SUPPLY CORPORATION (LIMITED).—This corporation was registered on the 30th ult., with a capital of £100,000, divided into 19,900 ordinary and 100 founders' shares of £5 each, to carry on in the city of Westminster, or elsewhere, the business of an electric lighting company. The subscribers are :—

	Founders' Shares.
*Joseph Browne Martin, 2, Victoria-mansions	1
*Henry Kimber, M.P., York-street, Westminster	1
Sir J. R. Heron Maxwell, Bart., Carlton Club	1
*R. W. Wallace, 2, Harcourt-buildings, Temple, barrister	1
J. W. Hiscox, 3, Victoria-street, Westminster, contractor	1
W. H. Baker, 74, Vincent-square, Westminster, head master Baroness Burdett-Coutts School	1
H. A. Hunt, jun., 45, Parliament-street, surveyor	1

The number of directors is not to be less than 3, nor more than 7; qualification, 50 shares or £250 stock; remuneration, £200 per annum to the chairman, and £100 per annum to each director.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended July 6th, 1888, amounted to £4,740.

CADOGAN ELECTRIC LIGHT COMPANY (LIMITED).—This company announce their first issue of shares to the public in the form of 4,000 A (Preference) shares of £5 each, for additional capital, "to execute the increasing demands for the electric light in their district."

DIRECT UNITED STATES CABLE COMPANY.—At a meeting of the Board of this company it was resolved to recommend a final dividend of 2s. per share, free of income-tax, such dividend to be payable on and after July 21st inst., making, with the interim dividend already paid, 2 per cent. for the year ended June 30 last. Recourse will be had to the reserve fund account to make up the required amount for such dividend.

GREAT NORTHERN TELEGRAPH COMPANY.—Traffic returns :—Receipts in June, 1888, £23,600; January 1 to June 30, 1888, £132,000. Corresponding months 1887, £127,120; corresponding month 1886, £124,560.

THE INDIA RUBBER, GUTTA PERCHA, AND TELEGRAPH WORKS COMPANY (LIMITED).—Notice is given that a half-yearly general meeting of this company will be held at the Cannon-street Hotel, London, on Thursday, the 19th inst., at 12 o'clock noon, for the purpose of obtaining the sanction of the shareholders to the payment of an interim dividend of 5 per cent., or 10s. per share, free of income-tax. The company's share register will be closed from the 12th to the 19th inst., both days included.

RAILWAY AND DOMESTIC ELECTRIC LIGHTING COMPANY.—A petition for the winding-up of this company has been presented to the High Court of Justice, and will be heard on the 14th inst.

TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY.—The transfer books of this company are closed from the 9th to the 17th, preparatory to the payment of an ad interim dividend of 12s. per share to all shareholders on the register.

THE WEST AFRICAN TELEGRAPH COMPANY.—With the sum brought down, the gross receipts of this company for the year ended December were £55.268, and the general expenditure was £21,586, leaving a balance of £33,681, from which has to be deducted debenture interest, £10,000 for repairs and renewal account, £500 for preliminary expenses, and £3,500 carried to a debenture redemption account. The directors now recommend a dividend of 3s. per share, leaving £1,215 to be carried forward.

THE WEST COAST OF AMERICA TELEGRAPH COMPANY.—The directors of this company have declared an interim dividend of 4s. per share, free of income-tax, in respect of the first half of 1888, payable the 23rd inst.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended July 6th, 1888, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company, were £3,958.

Offices—**WINCHESTER HOUSE, OLD BROAD STREET, LONDON, E.C.**

The principal objects of the Corporation are:—

1. Performing the duties of Trustee, Executor and Administrator.
2. The Insurance of Bonds, Shares and all other Securities lodged with the Corporation against risks of all kinds.
3. The Issue of Warrants and Certificates against Securities deposited, and making and procuring advances on such Warrants.

The Office of Trustee or Executor is to private persons usually a thankless post, involving much anxiety, time and money, and frequently leads to serious actual loss; whilst death, illness and change of residence necessitate frequent fresh appointments, and consequent expense to the parties interested. The Corporation undertakes all the duties of Executor, Trustee or Administrator for reasonable remuneration proportioned to the work and responsibility in each case.

The Corporation insures existing Trustees and Executors against all risks attending those positions, where the business is conducted by the Solicitors to their Trusts under the supervision of the Corporation, it not being the desire of the Corporation to interfere in any way with the duties of the family solicitor.

The Corporation acts as Trustees for the Debenture Holders in Public Companies.

For terms, &c., application should be made to the General Manager at the Company's Office.

GEORGE PEARSON, *General Manager and Secretary.*

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL SCIENCE, INDUSTRY AND ENGINEERING.

No. 531.—Vol. XXI. FRIDAY, JULY 20, 1888. Price 4d.

NOTES.

Mr. Justice Kay delivered judgment in the case of the Edison-Swan Electric Lighting Company *versus* Holland and others on Monday last. The full text of the judgment will be found in our columns this week. Probably most of our readers are already aware that the Edison patent has been upset, while the Cheesborough patent is maintained. We understand that the counter action brought by the Anglo-American Brush Corporation against the Edison-Swan Company for alleged infringement of the Lane-Fox patents for the manufacture of incandescent lamps, and also for the working of dynamo lamps and accumulators all in parallel, will not come before the Courts until after the Long Vacation.

The litigation which has just resulted in the loss of two important monopolies is the first break in the long series of triumphs which have been won by the holders of electrical patents in this country in maintaining the legal rights conferred upon them by the Patent Office. Possession is proverbially nine points of the law, and it is hardly to be wondered at that a feeling existed in electrical circles that in actions for infringement the odds were largely in favour of the patentees. From an abstract point of view this feeling is by no means to be regretted, for every invalidation of a patent is a tacit reproof to the Patent Office—or, rather, to the patent law—which leaves the patentee to discover whether the protection it professes to confer is worth the paper on which it is written. Under the existing *régime* the English patent law is as much a lottery as the Government lotteries of France or Italy. For our own part we are inclined to think that a deplorable mistake was made when "the poor inventor" was encouraged to seek a delusive protection by diminishing the cost. Far better would it have been to have raised the charges still higher, and by inaugurating a rigorous search for anticipations to have placed an English patent upon a level with those of the United States or of Germany. Had this been the case it is in the highest degree improbable that either "Gaulard and Gibbs *v.* Ferranti" or "Edison-Swan *v.* Holland and Others" would ever have found its way into the courts.

In this connection it is curious to note that, notwithstanding the admitted superiority of the American patent law—to some extent, in fact, by virtue of that superiority—electric lighting patents have not, upon the whole, experienced good fortune in the United States. Attempts were made both on the part of Siemens and of Gramme to obtain patents which would have virtually controlled the manufacture of the modern type of dynamo machines, but in each case the application was frustrated by being delayed beyond the period allowed by the law. The Brush Company failed to sustain its patent on the arc lamp owing to proof of a prior public use, although on a very small scale; and still more recently some of the Edison incandescent lamp patents have come to grief in the States. By-the-bye, we hear nothing further about the alleged intention of the Edison Company to enforce their patent for parallel working in America. This is a patent well worth possessing if it can be made good.

We have often thought Mr. Edison a great inventor in more ways than one, but we have always been sure that his business agents were equal if not superior to him in ingenuity. Of this latter one piece of evidence lies before us in the shape of a circular signed on behalf of the American Edison Electric Light Company by Mr. E. H. Johnson, its president. A rival company, the Westinghouse, having submitted its system to exhaustive tests which were not made public, the method adopted by the Edison man of business to improve the occasion is to inform all the Edison agents that the tests had been made at the instance of the United Gas Improvement Company, who had rejected the Westinghouse system because those tests had proved its inferiority to the Edison system. All this is clearly implied in the Edison circular, and the agents are advised to go in and win on the strength of it; but, at the same time, so carefully guarded is the wording of the document that a court of law would find it hard to convict the writer of a worse offence than that of printing rash and impudent conjectures which had no foundation in fact. The Westinghouse Company reply by publishing flat denials, both from the gas company referred to and from Prof. Morton, who instituted the tests. Business is one of the sciences in the States, and it is impossible to deny the very exalted position to which the Edison scientists have already attained.

As a pendant to this passage of arms we are tempted to quote an advertisement which has recently been issued by the United States Electric Lighting Company. It will be remembered that this company recently succeeded in defending an action brought by the Edison Electric Lighting Company for infringement of patents, the alleged infringement being justified on the purely technical ground that the patent had expired

Digitized by Google

owing to the non-renewal of a certain foreign patent embodying the same claim. This plea was, no doubt, good enough for the lawyers, but the victory scarcely seems one to be proud of. Under these circumstances, we are unable to feel much sympathy with the remonstrances contained in the advertisement alluded to, which *verbatim et literatim* reads as follows :—

"EDISON *vs.* THE UNITED STATES ELECTRIC LIGHTING CO.

"'Whom the Gods would destroy
They first make mad.'

"The anger of the Edison Company [*of New York*], since being beaten at law, is forcibly manifested by a 'Confidential Circular to Edison Agents' containing alleged explanations as to why Edison was beaten at law, in which the dignified (!) president delivers himself of his wrath in a tirade of abuse, libelous and personal, against a most humble and unimportant individual, and produces the first 'patch' for the 'collapsed airship' as predicted in 'The Edison Boomerang' Circular.

"As the general public may desire to see this confidential circular, a large edition has been provided, and will be furnished in unlimited quantities, postage prepaid, upon application to

"THE UNITED STATES ELECTRIC LIGHTING CO."

In this case it appears to us that the Edison Company is more sinned against than sinning.

On a careful review of the financial results which have attended the working of the Post Office Telegraphs our contemporary *Engineering* arrived last week at three conclusions: First, that the management by Government officials compares unfavourably with that of private individuals; secondly, that the *employés* are inadequately paid; and, lastly, that Parliament must take the whole matter in hand so as to place British Government telegraphy upon a sounder basis. Now, as it is the habit of private firms to starve their servants when profits are low, and that this is admittedly what the Government is doing in respect to the telegraph service, it is hard to understand where the unfavourable comparison comes in; and when it is remembered that the present unsatisfactory state of the Post Office Telegraph's finances is chiefly due to the interference of Parliament, the prospect of improving them by further interference from the same quarter seems very remote indeed.

These three conclusions are, in fact, mutually destructive, and our contemporary has arrived at them by laying on the shoulders of the permanent officials the responsibility which rests entirely with Parliament. It was Parliament, and not the Post Office, that demanded extensions which could never be remunerative; it was the Treasury which insisted on the cost of these extensions and the consequent increased cost of working being charged to revenue instead of to capital. Finally, it was not the Post Office officials, but their Parliamentary chiefs, backed by Parliament itself, that prematurely forced the unprofitable experiment of sixpenny telegrams—an experiment which, roughly speaking, has caused the expenditure to increase about twice as fast as the receipts. On the other hand, we owe it to the Post Office that the sixpenny tariff has not proved so disastrous as Parliament would have made it. Sixpenny telegrams were yielded to Parliamentary clamour; but that the number of words was reduced, and, above all, the free addresses abolished, was entirely due to the firm stand made by the permanent officials. It is true, as our contemporary remarks, that the so-called sixpenny telegram often costs eightpence or tenpence; but this circumstance only shows how very much worse its financial condition would have been had the Post Office allowed Parliamentary pedants and faddists to have had their way.

According to a pamphlet just issued by the *Financial News* the prospects of copper are more hopeful than one would imagine, the price being kept up artificially by an expenditure which must soon exhaust the resources of the syndicate. The present demand by consumers is being largely supplied by the free smelters, while the stock of the Copper Ring is being enormously augmented without the least possibility of their selling it for what it has cost them to buy.

In an early issue we shall give some account of the electric lighting station at Leamington, which we have recently visited. Meanwhile we take the earliest opportunity of confirming the statements made by Messrs. Chamberlain and Hookham, in a letter which we published on the 1st ult., to the effect that the unmitigated abuse which has been showered upon them at the meetings of the Town Council has largely proceeded from "political" motives. From the enquiries which we have made upon the spot it is sufficiently clear that a certain section of the local "politicians" (save the mark!) were from the outset determined to stigmatise the electric lighting as a failure. Unfortunately, whether by accident or otherwise—and really the latter alternative seems to be more than probable—a series of insulation faults occurred during the first few months of the enterprise, the origin of which has never been satisfactorily explained. The opponents of the scheme were in this way furnished with plausible ground for their complaints. But it is a fact, for which Messrs. Chamberlain and Hookham should receive the fullest credit, that no hitch of any kind has occurred during the last eight months. We still think it unfortunate that Messrs. Chamberlain and Hookham permitted the allegations made against them in the Town Council, and also in some of the local papers, to remain so long without an answer. For although they were no doubt entitled to ignore these attacks so far as concerned themselves personally, yet it would have been well to have realised earlier that the interests of the electric lighting industry were being injuriously affected elsewhere. With regard to the street lighting, we can only say that we saw nothing at Leamington which has induced us to modify our opinion that—taking into consideration the public expectations—it is a mistaken policy to employ low candle-power incandescents for street-lighting.

So the Pilsen-Joel Company's business—patents and all—is put up for sale in the open market. In our issue of June 29th we reported that a joint committee of directors and shareholders had been entrusted with full powers to take this step if, after due examination, it was deemed advisable. We cannot regret the conclusion at which the committee has arrived, for it

Digitized by Google

has long been evident that under the present *régime* the company would scarcely achieve any great success. At the same time there is no doubt that the nucleus of a genuine business has been secured, and one which, under good management, might become an extensive and a profitable concern.

At the extraordinary general meeting of the shareholders of the MAXIM-WESTON COMPANY, held yesterday afternoon, five directors were added to the existing Board. This part of the business was settled amicably enough; but on the proposal to remunerate the Committee of Investigation, and the still more serious question of inviting Mr. HUGH WATT to retire from the Board, the meeting became a scene of admired disorder. A recommendation to divide £100 among the members of the committee was at length adopted; but the meeting broke up without any decision in respect to Mr. WATT.

The Electric Lighting Order Confirmation Bill.—This Bill was read a second time in the House of Lords on Monday, July 16th.

Exeter.—The Town Council of Exeter are advertising for tenders for lighting a portion of the city with arc lights. Further particulars may be found in our advertisement columns.

Proposed Central Station at Stamford Hill.—We understand that Mr. E. Fahrig has a scheme in hand for starting a central lighting station in the neighbourhood of Stamford Hill, and that there is a good prospect of success.

The South London Polytechnic Institutes.—Among the donations that have recently been promised towards the funds of the South London Institutes is one of £1,000 from the firm of Messrs. Rothschild, and a similar sum from Messrs. Baring.

Chelsea.—At the meeting of the Chelsea Vestry, on Tuesday week, a letter was read from the Chelsea Electricity Supply Company for the vestry's sanction to their proposed capital under Schedule A. The sum of £32,000 was mentioned, which the vestry considered sufficient.

An Electrical Politician.—From a Cape newspaper we learn that East Griqualand has done itself the distinguished honour of electing Mr. Sivewright (the joint author with Mr. W. H. Preece of the well-known text-book of telegraphy) as its representative in the Cape Parliament.

Halifax.—The Mayor of Halifax, on the application of the Schmidt-Douglas Electric Lighting Company, of Bradford, has promised to call a committee meeting of the Council on an early date to consider whether or not the principal streets of the town should be lighted by the electric light.

Madrid.—From references in the local papers it would appear that the native firms are showing considerable activity in introducing the electric light. It is stated that the Arenal, Preciados and other principal streets of Madrid, as well as the Senate House and offices of the Provisional Government, are to be lighted by the Sociedad Electrecista.

Freemasonry.—At the Provincial Grand Lodge of Middlesex, held at the Memorial Hall, Great Stanmore, on the 7th inst., the Provincial Grand Master, Colonel Sir Francis Burdett, Bart., was pleased to appoint and invest as his Junior Grand Warden for the ensuing twelvemonth W. Bro. Geo. Gregory, P.M. and Secretary of the Electric Lodge, No. 2,087.

The Proposed Polytechnic Institution for Chelsea.—A meeting in support of the movement to raise £50,000 for the establishment and endowment of a Polytechnic Institution for South-West London was held, under the presidency of Lord Cadogan, at Chelsea House, on Wednesday. The proposal met with hearty approval, and a resolution pledging the meeting to carry it into execution was agreed to.

Personal.—We learn that Mr. Antony Reckenzaun has been appointed as managing engineer to a department that Messrs. Woodhouse and Rawson (Limited) have formed for the application of electricity to the transmission of power and similar purposes. He has also been appointed as manager to the Woodhouse and Rawson Electric Manufacturing Company (Limited), in place of Mr. R. Archbould, who has unfortunately had to resign on account of ill-health.

Paris Exhibition, 1889.—We are glad to learn that there is every probability of the Industrial and Machinery Departments of the English Section being extremely well represented. The whole of the space has been applied for, and is now being allotted. But the Arts Section and the Agricultural Machinery Sections have received only scanty support. The Association of Agricultural Engineers have vetoed the Exhibition, and have left the trade of the Continent to their American and German rivals.

The Saunders Lightning Guard.—We have on several occasions recorded cases of cables which have been protected from damage by lightning owing to the efficiency of the Saunders lightning guard. The following are recent instances of its value:—On May 20th and again on June 28th, during severe storms at Marseilles, accompanied by lightning, the Eastern Telegraph Company's Bona cable was automatically put to earth at the cable house by the fusing of the platinum wire of the Saunders lightning guard.

Repairs to the Interrupted Telegraph Cables.—We are glad to announce that one of the Australian cables has been repaired, and the ship is now busy on the second. The company had chartered a third steamer to bridge over the break, but fortunately the line was put through in time to cancel the charter a few hours before the vessel was to sail. Two faults have been removed from the Anglo-American Brest cable, one in deep water, where the cable was in good condition, and the other near St. Pierre. The ship is now at work on the third and last fault.

Application for Provisional Orders for Lighting the Strand District.—At the last meeting of the Strand District Board of Works the Clerk reported having received the following notices of intended application for provisional orders to supply electricity for lighting, &c., in the area of this district, viz., the South Metropolitan Electric Supply Company, the Electrical Power Storage Company, London Electric Supply Corporation, the Westminster Electric Supply Corporation, and Messrs. Walter F. Glover and Co.; these were referred to the Lighting Committee for consideration and report.

Exeter.—At the last meeting of the Committee of the Exeter Town Council, the Town Clerk reported that notice had been given both to the owners of Trew's Weir Mills and to the Electric Lighting Company, and he had prepared the draft case, which he produced. He further reported that at the last meeting of the Council a letter was received from the Electric Lighting Company suggesting a conference, and that the Council had resolved that on the Company putting their proposals in writing the Committee be authorised to enter into the desired conference. Up to the present he had not received the company's reply. The further consideration of the matter was deferred.

Digitized by Google

Remarkable Items from the Daily Press.—A financial paper this week informs its readers that "the Grosvenor Gallery is to have the electric light, which will be supplied from a distant centre at Deptford, and will need a very powerful current, so strong that electricians doubt if it will be safe to handle the lines, the leakage from which might be sufficient to cause serious injury." In another paper we find that Mrs. Swan's garden party at Bromley is said to have been "given by Mr. Schwann, at his suburban residence in Balham." The effort of a Dublin journal to grapple with the meaning of electrolysis is, however, still better. We read "Electrolysis is chemical decomposition by means of electricity. When practised on the skin it is injurious to it. It requires complex electric machinery. Most Dublin physicians could have it done. It would not take long."

The London Chamber of Commerce and the Proposed Electrical Section.—A meeting of the members of the London Chamber of Commerce who are interested in the proposal to establish an electrical section was held at Botolph House, Eastcheap, on Friday afternoon last. About a dozen members were present, including Mr. Crompton (who occupied the chair), Messrs. Garcke, Applegarth, Alabaster, Gatehouse, Snell, Wilding, Price, Harold, Fraser, and Binswanger. The following resolutions were carried:—That the formation of an electrical section is desirable; that the members present form a provisional committee for the purpose of organising an electrical trades section; that meanwhile they use their best influence to induce their friends to join the section; and that a circular in the name of the provisional committee be issued to the trade inviting them to attend a meeting on the 27th of July.

Obituary.—We regret to announce the sudden death of Mr. W. H. Davies, Superintendant of the Eastern and South African Company's station at Zanzibar, after a short attack of fever. Mr. Davies leaves a widow and three children. He commenced his telegraphic career in the Electric and International Telegraph Company, and was some little time on board the steamer "Brisk" with Captain Barrow. He afterwards entered the service of the Falmouth and Gibraltar Telegraph Company (now the Eastern Telegraph Company), at their London office, Old Broad-street. From thence he was transferred to Carcavellos, Portugal, and was next appointed the Eastern and South African Telegraph Company's superintendent at Mozambique, and subsequently at Zanzibar, where he married the youngest daughter of Mr. L. Durand, of Lisbon, Mr. Davies' loss will be deeply regretted by a wide circle of friends. We believe that he held instructions from headquarters to proceed to Cape Town as superintendent, but his death, which took place on the 4th instant, unfortunately occurred on the eve of his departure.

Dublin Corporation and the Electric Light.—At the last meeting of the Dublin Town Council, Mr. Healy asked the Chairman of Committee of the Whole House on Electric Lighting what progress had been made, the date when orders were given to apply for license, if that license had been obtained, and, if not, to explain the cause of the delay. And, as the committee has been sitting from time to time since the 2nd May, 1887, if it would be advisable to throw more energy into the matter.—Mr. Robinson said that on May 2, 1887, a committee was appointed to investigate whether the water-power at Island Bridge was sufficient for electric lighting of thoroughfares, and was empowered to employ an expert. On October 10, 1887, a report of the committee was adopted that an application should be made for a license, and that was confirmed by resolution of Council on 12th December, 1887. On December 28th the committee instructed the borough surveyor to reconsider the specification. On 18th February the application for a memorial was forwarded by the Board of Trade. The week before last a meeting took place in London between representatives of the Gas Company and representatives of the Corporation, at which a practical agreement was come to.

Bradford, Yorks.—The Bradford Corporation, in view of its scheme for erecting a central generating station in Bolton Road, for providing a regular supply of electric light and power for Kirkgate, Market Street, and places in the immediate vicinity, has recently issued a circular to occupiers of business premises in the central portion of the borough, inquiring whether such occupiers would be disposed to take a supply of the current regularly for a stated period, suggested as three years. So far, there has been a fair response to the inquiry, though it is somewhat early to enable the Corporation to say to what extent the experiment is likely to succeed. With respect to price, the Corporation has determined to adopt an alternative system of charge for incandescent lamps, namely:—(1) 5d. per unit, the Corporation to supply meters, if desired, at a rental of 10 per cent. on the cost; (2) by an annual charge of 20s. per lamp of 16 candle-power, irrespective of the actual hours of lighting. The charge for the supply to arc lamps is to vary with the illuminating power of the lamp, as required by the consumer, at the rate of 5d. per unit. The Corporation proposes to carry the supply up to the buildings, the internal fittings being provided by the consumer.

Search Lights on Yachts.—We have received the following letters for publication:—"Sir: On behalf of a client I have made inquiries which have elicited a letter from the Assistant-Secretary of the Board of Trade, and since it is of interest to the profession I enclose a copy for publication in your columns.—Yours, &c., A. P. TROTTER."

"Board of Trade (Marine Department), London,
17th July, 1888.

"SIR: With reference to your letter of the 12th inst., asking under what conditions an electric search light may be used on board a yacht, I am directed by the Board of Trade to state that they are advised that the light in question cannot legally be carried or exhibited in the manner in which mast-head or side lights are carried and exhibited under Articles 2 to 11 of the 'Regulations for Preventing Collisions at Sea.'

"The Board are further advised that although by Article 23 of the said regulations a search light may perhaps be legally used under such special circumstances as may render a departure from the regulations necessary in order to avoid immediate danger, the question whether its use is justified by the special circumstances of any particular case is one that must be decided upon its merits in the event of any legal proceedings arising therefrom.—I am, Sir, your obedient servant,

"THOMAS GRAY."

Telegraphic Communication with Mauritius.—In the House of Commons, on Friday last, Sir E. Watkin asked the Under-Secretary for the Colonies whether the island of Mauritius, which had a naval dockyard, and the fortified harbour of St. Louis, was, like Bermuda, unconnected by submarine telegraphic cable, independent of foreign interference, with any other portion of the Empire; whether the Malagasy Government so long as three months ago expressed their readiness to assist in establishing direct communication through their territory with Great Britain by means of a cable from Mozambique, to be landed at Mojunga, and by the erection of a land line thence to the capital, and onwards to the east coast at Andevoranto or Vatomandry, with the right to connect the same by cable to Mauritius and whether he had come to any decision in the matter.—Sir J. Gorst, for Baron H. De Worms, said:—"There is no direct telegraphic communication with Mauritius, but messages are sent as opportunity offers by steam vessels from Aden

Digitized by Google

Natal, and Australia. The particular proposal referred to has not come under the consideration of Her Majesty's Government, but various schemes for laying a cable to Mauritius, *vid* Madagascar, have been, and still are, under consideration. It has not, however, been found possible to make provision for this service, and until arrangements can be made for meeting the cost of a cable, it is not possible to come to a decision as to the particular route."

The Electric Light Scheme at Bath.—The report of the Electric Lighting Committee of the Bath Town Council has been issued, giving particulars of the seven tenders received in answer to the advertisement for the lighting by electricity of the streets in the district approved by the Council. The report states, "All persons tendering concur in recommending the adoption of overhead in preference to underground wires, as being much less expensive and less liable to failure on account of defective insulation. There are three methods of fixing overhead wires—(1) on poles placed on house roofs, (2) on brackets placed on house fronts, (3) on lamp-posts in a line with the kerbstone placed from 100 to 150 feet apart. The last mentioned is the method recommended." The chief particulars of the different tenders are given in the table below. The committee have fully discussed the several tenders, and they are of opinion that the one sent in by Mr. Massingham presents great advantages, and that the small extension of the area to be lighted with electric light which it suggests (a plan of which can be seen at the town clerk's office) is well worthy the consideration of the Council.—At the meeting of the Town Council on Tuesday last, Mr. Sturges moved "That the tender sent in by Mr. Massingham for lighting the streets in the extended area therein mentioned with electric light be accepted for a period of seven years, and that it be referred to the Surveying Committee to enter into and superintend the carrying out of a contract accordingly." He remarked that Mr. Massingham's tender was the best and most advantageous. The recommendations in its favour were three-fold. The first recommendation was that the system he proposed to employ, the Thomson-Houston system, had been acknowledged in all competent trials to be the best. The next point was that Mr. Massingham's tender was the cheapest Thus they got the best system at the cheapest rate. Then there was a third point. The tender had not emanated from Mr. Massingham personally, but it came from a body of gentlemen who were their fellow citizens. These gentlemen came to the resolution that if the Town Council would introduce the electric light, they themselves would undertake the responsibility of starting a company. Circumstances now seemed to favour the early introduction of the electric light, and he urged that longer delay was unnecessary. The expense would not be frightful. He was able to say that they could have the electric light throughout the area indicated for an increase of £203 per annum on the present price paid. For that they would get 18 or 20 times the light, and if that was not a recommendation in favour of the electric light he did not know what was.—Alderman Murch seconded the motion, and Alderman Oliver opposed the adoption of the report. They were asked, he said, to do away in their lighting with an agent which they knew, and to adopt an agent of which they knew little or nothing. To his mind the matter had not yet received that ample discussion which the occasion required. He opposed the introduction of the light on the same grounds he did on a previous occasion, viz., that electricity was as yet in its infancy, and that it would not be safe for them to introduce it here, and that they had better wait a few years and then determine what course to take. He had watched very carefully the progress of the electric light for many years, and he said unhesitatingly its growth had not developed in such a manner as to justify them in saddling the ratepayers with the cost of its introduction. Did anyone suppose that towns like Birmingham, Manchester, and Liverpool, where there were experienced, far-seeing, intelligent, and go-a-head men in their councils, would not have adopted the light if it was so desirable as it was stated to be. At Leamington it was an admitted failure. As to the report presented that day, it was unsatisfactory, inasmuch as it gave no information with regard to cost or as to the number of lamps which were to be displaced. Seventy lights were to be furnished for fifty streets. That seemed a rather small number, and his own feeling was that it was not anything like sufficient, and they would find eventually that it was not sufficient. Then they were told the lamps were to be from 100ft. to 150ft. apart. He had not measured the distance, but was of the impression that seventy lamps would not cover the area, and that they would be called upon again. He hoped the Council would never sanction overhead wires owing to the great danger arising therefrom. People would wonder how it was that if the electric light at Eastbourne cost double the amount of gas it became cheaper in Bath. By extinguishing 273 lamps and replacing them by 70 electric lights they were only giving one and a-quarter lights to every four gas lamps. In other towns they gave one electric light to every three lamps. According to Mr. Sturges' figures the cost would be £368, but in the report it was £203. How the difference arose he had yet to learn. The introduction of the electric light would increase the rates in a way which he did not think would be advantageous. Do not let them be in a hurry.—Alderman Gibbs urged that the matter could be very well put off for a long time to come.—Ultimately, on the motion of Mr. Radway, the question was adjourned until Tuesday next.

SOME ENGLISH CENTRAL LIGHTING STATIONS.*

IV.—THE CADOGAN STATION AT CHELSEA.

The central lighting station of the Cadogan Electric Lighting Company at Chelsea is at 91, Manor-street, not far from the river bank, and near the Albert Bridge. The situation is convenient for the transfer of coal and ashes, and for a high-tension system of distribution it is sufficiently near the district which it is contemplated to serve. This district includes Chelsea, South Kensington, Brompton, and Knightsbridge, and as it comprises buildings of almost every class, from an electric lighting point of view it ought eventually to give a favourable curve of output. In commencing operations the company very wisely decided to start upon a modest scale, but to lay out their plans in such a way as to permit of subsequent extension without interference with the plant already at work. To this end it was deemed indispensable at the outset to erect a station capable of containing plant for supplying at least 50,000 lamps. The consequence is that we have now at Chelsea one of the best designed and most spacious buildings which has yet been erected in this country for the purpose of central station electric lighting. Below we give some of the dimensions in detail. The whole of the plant has been laid down and the circuits have been built under the sole superintendence of Mr. J. S. Sayer, the managing director of the company.

As we have already intimated, the system of distribution is that of high tension in the mains. It is, in fact, what Mr. Crompton calls a B.T. system, but is carried out in a much more thorough manner than has yet been done elsewhere, even by Mr. Crompton himself. Unlike Kensington Court, where the batteries are, for the present at any rate, confined to the station itself, every consumer at Chelsea has his own secondary battery, which is charged from the main conductor in series with the rest. The system adopted has therefore all the merits and all the defects of distribution by batteries, and by the behaviour of the cells its success will be chiefly determined. Some important modifications in the method of working have, however, been introduced by Mr. Edmunds, as described below, and which we should be disposed to value more highly if the employment of automatic switches in each installation were not involved. However, we shall be glad to see Mr. Edmund's device receive a fair trial, and shall then be prepared to judge it on its own merits.

Both engines and dynamos have been supplied by Greenwood and Batley, of Leeds. The engines are of the well-known Armington-Sims type, which are so largely used for electric lighting in America, and for which Greenwood and Batley are the sole agents in this country. With these preliminary remarks we proceed to give the following details :—

Station.—The area of the engine room is 90ft. by 90ft., and the space available is sufficient for a 50,000-light plant; it is provided with a 10,000-gallon water tank and a coal house of 40 tons capacity. There are also spacious offices and store rooms, all situated upon the ground floor. The building was designed by Mr. Sayer and erected by Messrs. Trollope and Sons, of Pimlico.

Engines and Boilers.—The plant at present consists of three 50 horse-power Armington-Sims engines, with 12in. stroke, cylinders 9½in. by 12in., running at 300 revolutions per minute, made by Messrs. Greenwood and Batley, of Leeds. The boilers are two in number and are of the Babcock and Wilcox water tubular pattern, each working up to 104 horse-power. The boilers are supplied with water from a pair of Worthington pumps. The steam exhaust from the engines is passed through a water heater, whence water is pumped into the boilers. The products of combustion are carried up an iron smoke stack 70ft. high and 4ft. 6in. in diameter. It is intended later on to fit the engines with electrical governors.

Dynamos.—The dynamos are three in number, made by Messrs. Greenwood and Batley and designed by Mr. Jones. These machines are of the single horseshoe type, and are series wound; running at 800 revolutions per minute, they have an output of 35 units (70 amperes and 500 volts). The field-magnets are separately excited by a battery of accumulators. This arrangement is alleged to be more economical than using a small dynamo exciter, and the separate excitation permits the three machines to be run in series, and obviates all danger of reversal. For our own part we should have preferred the use of shunt-wound machines, which, although costing somewhat more for the field winding, would have given nearly automatic regulation for constant current. Owing, however, to the fact that the machines do not deliver current to the lamps, the regulation is a matter of secondary importance, and is easily effected by means of resistance coils in the field-magnet circuit, which are adjusted by hand.

Batteries.—Each consumer has a set of accumulators, which are charged in series, and which by an ingenious device, referred to below, can, if required, be used by the consumer whilst the charging current is on. The cells are of the new pattern E.P.S., 31L type, of 700 ampere-hour capacity. The number of cells in each installation varies from 8 to 64, according to the number of lamps. The circuit is worked upon the "Edmunds's distributing system," now introduced for the first time. The accumulators at each house are arranged in four sets, three of which are always in series on the lamps, and the fourth is on the charging mains. A small electric motor actuates a switch, which at intervals of one, two, or three minutes, as may be required, switches one set of cells off the lamps and on to the mains; each of the four sets is thus charged at equal intervals for equal periods. During the brief space of time when all four sets are on to the lamps, a resistance is simultaneously placed in series with them. By this device the total E.M.F. on the charging mains is diminished to one-third of the amount which would otherwise be necessary; but the total duration of charging is, of course, spread over a correspondingly longer period. Combined with this distributor is a new coulomb-meter, which, together with the distribution itself, we shall describe more fully as soon as the patents have been completed.

Cables.—The main circuit is a simple series one, seven miles long out and home. The furthest point supplied is Belgrave-square. The circuit is at present entirely overhead, though before long some portion will be placed underground along the Chelsea Embankment. The cable, a 19/14 strand, made by Messrs. Glover and Co., is suspended from a 7-strand steel wire, with standards at intervals of about 70 yards.

Lamps.—The total number of lamps at present in work is 965, though in a short space of time it is expected that there will be a total of 2,500 connected. The lamps used are Edison-Swan 16 candle-power, their voltage varying from 12 to 96 volts, according to the size of the installation. The largest private installation on the mains is that in the house of Mr. Reuben Sassoon, where 350 lights are wired.

NOTES ON ALTERNATE CURRENTS.

BY J. A. FLEMING, M.A. D.SC.

(Continued from page 143.)

Mutual Induction of Two Circuits of Constant Inductance.—We will conclude this chapter on the theory of simple periodic currents moving in circuits of constant inductance by examining the mutual induction between two circuits in one of which a simple periodic electromotive force operates. We suppose two circuits to be so placed relatively to each other that when a change of current occurs in one, which is called the Primary (Pr.), a change of magnetic induction takes place through the other, called the Secondary (Sec.). We have then to regard the primary and secondary as linked together by loops of induction and the closed lines of induction, together with the two circuits must be considered as forming three links of a chain. We shall suppose the self and mutual inductance to be known, as also the resist-

Digitized by Google

ance of each circuit. The primary inductance and resistance will be denoted by L and R, and those of the secondary by N and S, and the mutual inductance by M. The primary is to be subjected to a simple periodic electromotive force of which the maximum value is E, and the result is to generate in the primary circuit a primary current, which, as we have seen, is also a simple periodic quantity, and is to be denoted by its maximum value, I_1. The change of induction through the secondary follows the change of current, and gives rise to an impressed electromotive force in the secondary circuit, which, being represented by the rate of change of the simple periodic induction, is also a simple periodic quantity, and gives rise to a simple periodic current in the secondary, to be denoted by its maximum value I_2.

The general description of the phenomena produced in such a system of primary and secondary circuits connected by an air magnetic circuit is as follows:—

1. The application of a simple periodic impressed electromotive force, E, produces a simple periodic current, I_1, moving under an effective electromotive force, $R I_1$, and brings into existence a counter electromotive force of self-induction, which causes the primary current I_1 to lag behind E by an angle called the primary lag θ_1. If n is the frequency of the vibrations and $2\pi n = p$, as before, then, as we have before seen, $\tan \theta_1 = \frac{Lp}{R}$, and this counter electromotive force of self-induction is a periodic quantity of which the maximum is $Lp I_1$, and of which the phase is 90° behind that of the effective electromotive force or current, or is in quadrature with it.*

2. The field round the primary, and therefore the induction through the secondary, is in consonance with the primary current I_1; but since it is also a simple periodic quantity its time-rate of change, and therefore the impressed electromotive force in the secondary, is in quadrature with the primary current. Since the induction through the secondary, due to a current, I_1, in the primary, is $M I_1$, by the definition of M the maximum value of the rate of change of this induction for a pulsation p is $Mp I_1$.

It is useful to note that in all dealings with simple periodic quantities, if X is the maximum value of a simple periodic quantity which runs through its cycle n times in a second, the maximum value of its time rate of change is denoted by pX where $p = 2\pi n$.

If, then, as usual, simple periodic quantities are denoted by the letter signifying their maximum values, prefixing p to any one gives us the value of its first differential with regard to time, or p is equivalent in notation to $\frac{d}{dt}$.

3. This secondary impressed electromotive force gives rise to a secondary current, I_2, moving under an effective secondary electromotive force, $S I_2$, and creating a counter electromotive force of self-induction in the secondary, represented by $Np I_2$.

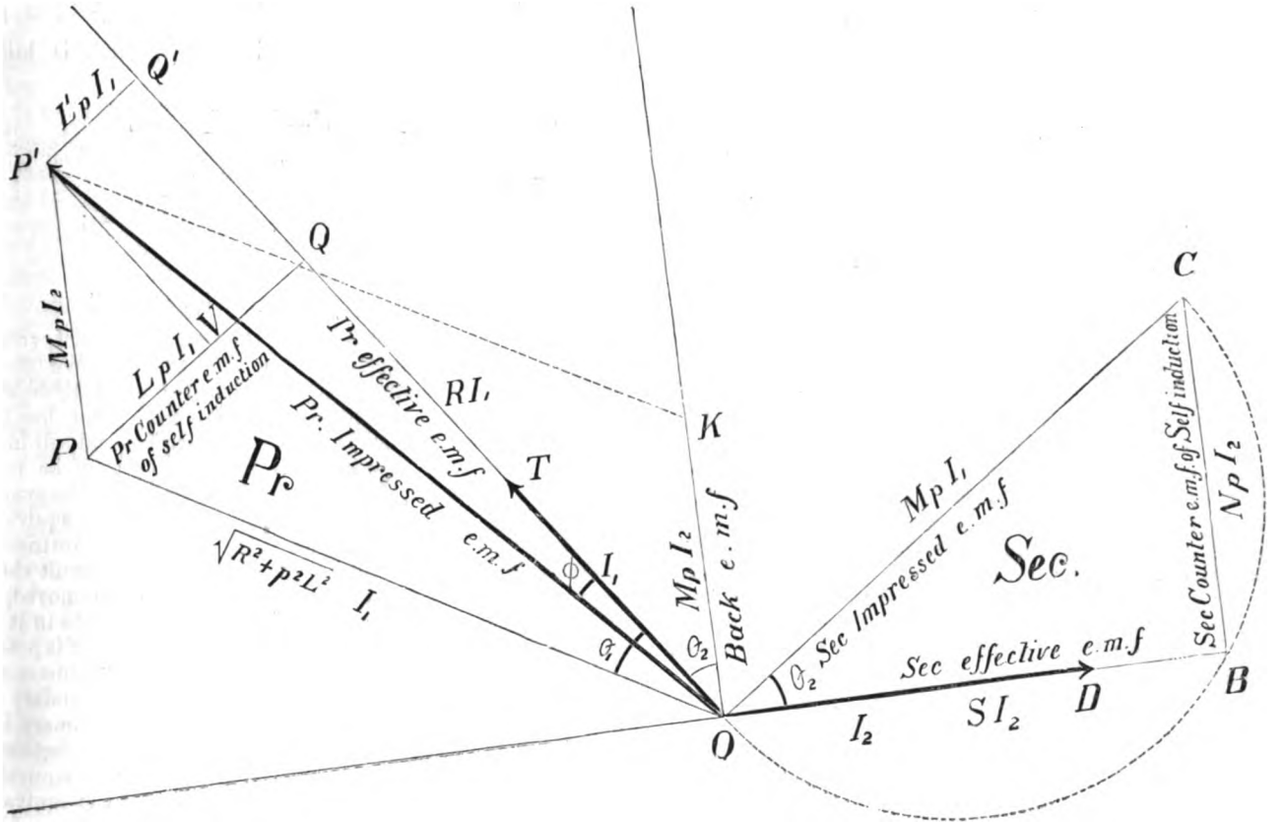

FIG. 40.—Electromotive Force Diagram for a Pair of Mutually Inductive Circuits.

The secondary current lags behind the secondary impressed electromotive force by an angle, θ_2, such that

$$\tan \theta_2 = \frac{Np}{S}.$$

4. This secondary current, I_2, reacts in its turn on the primary, and it creates what is called a back electromotive force, or reacting inductive electromotive force on the primary circuit. The phase of this must be in consonance with that of the electromotive force of self-induction in the secondary, and it is represented by the quantity $M I_2 p$. This is obviously in quadrature with the phase of the secondary current or secondary effective electromotive force.

5. There is, then, a phase difference between the primary and secondary currents, and also between the primary impressed electromotive force and the primary current.

The general problem is, then; given the value of the inductances L, M, N, and the resistances R, S, and that of the impressed electromotive force E and the frequency n, find from these seven quantities other four, viz., the primary current I_1,

* Mr. T. H. Blakesley has employed the term *in quadrature* to express the fact that one simple periodic quantity lags 90° behind another; hence the electromotive force of self-induction is said to be *in quadrature* with the effective electromotive force or current.—*See* T. H. Blakesley, "On Magnetic Lag," *Phil. Mag.*, July, 1888.

Digitized by Google

the secondary I_2, and the difference of phase between E, I_1 and I_2.

We shall attack the problem geometrically, as this method exhibits far better than the algebraic method the relation between the various quantities involved. The method adopted is to construct an electromotive force diagram, in which all lines represent on any scale volts; and moreover as each of the quantities considered is a periodic quantity, the lines all represent the maximum value of each quantity, and the value at any instant can be obtained by taking the projections of all lines on any straight line through the centre of the diagram suitably placed.

Let O (Fig. 40) be taken as a centre; draw any line O Q', and on it set off any length, O T, which we *assume* as the magnitude of the maximum of the primary current. All other lines will be in proper proportion to this. Produce O T to O Q so that $O Q = R I_1$. O Q is then the effective electromotive in the primary circuit. From Q draw Q P at right angles to O Q, and set off Q P equal to $L p$ times O T or to $L p I_1$; Q P represents the electromotive force of self-induction in the primary circuit. Join O P.

From O draw O C at right angles to O Q, and set off O C equal to $M p$ times O T. O C is then equal to $M p I_1$, and O C represents the impressed electromotive force in the secondary circuit. On O C describe a semi-circle, and set off O B, making an angle C O B with O C such that $\tan C O B = \frac{N p}{S}$, or tan C O B = the ratio of the inductive to the ohmic resistance for the secondary circuit. Join B C. On the same scale on which O C represents the impressed electromotive force in the secondary circuit, viz., $M p I_2$, O B will then represent the effective electromotive force in the secondary, or will represent $S I_2$, and hence if O D is taken equal to one S^{th} part of O B, O D will represent I_2, or the secondary current. Next draw a line O K perpendicular to O B, and therefore parallel to B C, and on it set off a length, O K, equal to $M p$ times O D or to $M p I_2$. O K represents then the back inductive electromotive force of the secondary on the primary.

The impressed electromotive force which has to be applied to the primary to produce in it the primary current O T and induce in the secondary the secondary current O D has therefore to be equal and opposite to the resultant of three electromotive forces, or to equilibrate three electromotive forces, viz., the effective electromotive force of the primary O Q, the electromotive force of self-induction in the primary P Q, and the back electromotive force in the primary due to the inductive effect of the secondary on the primary, viz., O K.

The resultant of O Q and Q P is O P. If, then, we draw P P' from P, and make it equal and parallel to O K, and join O P', O P' will be the resultant of O Q, Q P, and O K; and hence O P' will represent E, or the impressed electromotive force required to be applied to the primary to maintain the currents I_1 and I_2.

It is to be understood that in this diagram a unit of length stands for a volt, an ampere, an ohm, and a secohm; and hence, on that assumption, E represents in volts the impressed E.M.F.—that is, the maximum of the simple periodic E.M.F. required to maintain the currents I_1 I_2, of which O T, O D represent the maximum values. The relative phases are indicated by the positions of these lines. To obtain the actual values of the E.M.F. and currents at any instant we have only to take the projections of O P', O T, and O D on any line drawn through O suitably placed, and the magnitudes of these projections will give the required quantities. We may consider the two right-angled triangles O Q P, O B C as pivoted together at O, and revolving round O; the fluctuations of the projections of O P', O T, O D on any line will give us the cyclic values of E, I_1, and I_2. We can next obtain some useful relations between these quantities from the geometry of the figure. In the triangle O B C,

$$O C^2 = O B^2 + B C^2.$$

Hence,
$$I_1^2 M^2 p^2 = S^2 I_2^2 + N^2 p^2 I_2^2;$$

or
$$\frac{I_1}{I_2} = \frac{\sqrt{S^2 + p^2 N^2}}{M p};$$

or
$$\frac{\text{primary current}}{\text{secondary current}} = \frac{\text{impedance of secondary}}{M p}.$$

$M p$ might by analogy be called the mutual inductive resistance.

To obtain the value of I_1 in terms of E, and the inductances and resistances, we project the lines O P' and O P on the vertical line O K, and express the fact that O P' or E is in all cases the resultant of O K and O P. Let the angle P' O Q' be called ϕ. ϕ is the angle by which the primary current lags behind the total impressed electromotive force. Then C O B is θ_2, and T O K = C O B = θ_2, since Q O C and K O B are both right angles.

Hence we have by resolution on O K

$$E \cos(\phi + \theta_2) = M p I_2 + \sqrt{R^2 + p^2 L^2}\, I_1 \cos(\theta_1 + \theta_2);$$

but since
$$I_2 = I_1 \frac{M p}{\sqrt{S^2 + p^2 N^2}}$$

we have by substitution

$$E \cos(\phi + \theta_2) = \left\{ \frac{M^2 p^2}{\sqrt{S^2 + p^2 N^2}} + \sqrt{R^2 + p^2 L^2} \cos(\theta_1 + \theta_2 \right\} I_1,$$

a relation established between E and I_1, which is known when ϕ is known.

Since
$$\tan \theta_1 = \frac{p L}{R}, \text{ and } \tan \theta_2 = \frac{p N}{S},$$

it follows by an easy transformation that

$$\cos(\theta_1 + \theta_2) = \frac{R S - p^2 L N}{\sqrt{R^2 + p^2 L^2}\sqrt{S^2 + p^2 N^2}};$$

hence
$$E = \frac{M^2 p^2 + R^2 - p^2 L N}{\sqrt{S^2 + p^2 N^2}} \frac{I_1}{\cos(\phi + \theta_2)}.$$

To find the value of ϕ, suppose that whilst E and I_1 remain the same the secondary circuit is suppressed. We should then only have an impressed electromotive force, E, creating a current, I_1, and from the diagram and from what has been before explained it is obvious that the effective and self-inductive electromotive forces in the circuit would then be represented by O Q' and Q' P'. If we denote these by the symbols $R' I_1$ and $L' p I_1$ we may properly call R' and L' the equivalent resistance and inductance; that is to say, these quantities are the resistance and inductance which the primary circuit should have in order that, when the secondary circuit is removed, the primary impressed electromotive force may generate in it the same current which it does when the secondary circuit is present and the primary has its natural resistance R, and inductance L. We see, then, that the effect of bringing up the secondary and allowing it to be acted upon and react upon the primary is to increase the effective resistance and diminish the effective inductance of the primary; in other words, the equivalent resistance of the primary circuit is greater and the equivalent inductance is less by reason of the presence of the secondary circuit.

We have then to find the value of $\cos(\phi + \theta_2)$.

$$\cos(\phi + \theta_2) = \cos\phi \cos\theta_2 - \sin\phi \sin\theta_2;$$

but
$$\cos\phi = \frac{R'}{\sqrt{R'^2 + p^2 L'^2}}, \qquad \sin\phi = \frac{L' p}{\sqrt{R'^2 + p^2 L'^2}},$$

and
$$\cos\theta_2 = \frac{S}{\sqrt{S^2 + p^2 N^2}}, \qquad \sin\theta_2 = \frac{N p}{\sqrt{S^2 + p^2 N^2}};$$

hence
$$\cos(\phi + \theta_2) = \frac{R' S - L' N p^2}{\sqrt{S^2 + p^2 N^2}\ \sqrt{R'^2 + p^2 L'^2}}.$$

Substituting this in the equation connecting E and I_1 we arrive at

$$E = I_1 \frac{(M^2 p^2 + R S - p^2 L N)\ \sqrt{R'^2 + p^2 L'^2}}{R' S - L' N p^2}.$$

Returning to Fig. 40, we see from it that P' Q' is parallel to P Q, and hence, if we draw P' V parallel to Q' Q, we have

$$P' Q' = P Q - P V$$
$$= P Q - P P' \cos P' P V$$
$$= P Q - P P' \sin \theta_2,$$

Digitized by Google

or $$L' p I_1 = L p I - M p I_2 \frac{N p I_2}{M p I_1};$$

or, since $$\frac{I_2^2}{I_1^2} = \frac{M^2 p^2}{S^2 + p^2 N^2},$$

we have $$L' = L - \frac{N M^2 p^2}{S^2 + p^2 N^2} \quad \ldots\ldots \quad (A)$$

Also, again, O Q represents $R I_1$ and O Q′ on the same scale $R' I_1$, and

$$\begin{aligned} O Q' &= O Q + Q Q' \\ &= O Q + P' V \\ &= O Q + P P' \sin P' P V \\ &= O Q + P P' \cos \theta_2; \end{aligned}$$

hence $$R' I_1 = R I_1 + M p I_2 \frac{S I_2}{M p I_1};$$

and therefore $$R' = R + \frac{M^2 p^2 S}{S^2 + p^2 N^2} \quad \ldots\ldots \quad (B)$$

These formulæ (A) and (B) give us the effective inductance and resistance of the primary circuit as affected by the secondary. They were given by Clerk Maxwell in a Paper in the *Transactions* of the Royal Society in 1865.

If we form from (A) and (B) the function $R' S - L' N p$, we find it to be $M^2 p^2 + R S - p^2 L N$; and hence, by substitution in the expression already given, connecting E and I_1, we arrive finally at the result

$$E = I_1 \sqrt{R'^2 + p^2 L'^2},$$

or $$I = \frac{E}{\sqrt{R'^2 + p^2 L'^2}}.$$

Following the usual nomenclature, we may call the expression $\sqrt{R'^2 + p^2 L'^2}$ the *equivalent impedance* of the primary circuit, and we have as the final result for the induction coil of constant inductance

$$\text{Primary current strength} = \frac{\text{impressed electromotive force}}{\text{equivalent impedance of primary circuit}},$$

$$\text{Secondary current strength} = M p \times \frac{\text{primary current}}{\text{impedance of secondary circuit}},$$

The angle of lag of primary current behind impressed E.M.F $= \phi$ tan $\phi = \frac{p L'}{R'}$, and the angle of lag of the secondary current behind the primary is seen to be $90° + \theta_2$ and tan $\theta_2 = \frac{N p}{S}$; hence we have the values and relative phases of the currents and the impressed electromotive force.

In the above equations we are to understand current strengths and electromotive forces to be either the maximum values or the average values during the period. If i_1 and i_2 be the actual values at any time t, reckoned from the instant of the maximum value of the electromotive force, then, from the principles previously explained in this chapter, it is obvious that

$$i_1 = I_1 \sin (p t - \phi),$$

or $$i_1 = \frac{E}{\sqrt{R'^2 + p^2 L'^2}} \sin (p t - \phi),$$

and $$i_2 = \frac{M p i_1}{\sqrt{S^2 + p^2 N^2}};$$

or, $$i_2 = \frac{M p}{\sqrt{S^2 + p^2 N^2}} \frac{E}{\sqrt{R'^2 + p^2 L'^2}} \sin (p t + \phi + \theta_2 + 90).$$

This series of articles on "Alternate Currents" will be continued in the autumn, when the practical measurements of self and mutual induction and the practical cases of mutual induction of circuits embracing iron or magnetisable cores will form the subjects to be treated.

The London Telephone Service.—The United Telephone Company have now made arrangements to keep their exchange service open day and night, including Sundays.

THE VOLTAIC BALANCE.

BY DR. G. GORE, F.R.S.

A new and simple lecture experiment. Take two small clean glass cups containing distilled water; simultaneously immerse in each a small voltaic couple, composed of either unamalgamated zinc or magnesium with platinum, taking care that the two pieces of each metal are cut from the same piece and are perfectly clean and alike. Oppose the currents of the two couples to each other through a sufficiently sensitive galvanometer, so that they balance each other and the needle does not move. Now dip the end of a slender glass rod into a very weak aqueous solution of chlorine, bromine, iodine, or hydrochloric acid, and then into the water of one of the cups. The voltaic balance is at once upset, as indicated by the movement of the needle, and may be shown to a large audience by means of the usual contrivances.

The chief circumstance to be noticed is the extremely great degree of sensitiveness of the arrangement in certain cases—this is shown by the following instances of the minimum proportions of substance required to upset the balance with an ordinary astatic galvanometer of 100 ohms resistance, and with a Thomson's reflecting one of 3,040 ohms resistance.

1. *Zinc and Platinum with Iodine.*—With the astatic galvanometer, between 1 part of iodine in 3,100,000 and 3,520,970 parts of water.

2. *Zinc and Platinum with Hydrochloric Ac'd.*—With the astatic galvanometer between 1 in 9,300,000 and 9,388,185 parts; and with the reflecting one between 1 in 15,500,000 and 23,250,000 parts.

3. *Magnesium and Platinum with Bromine.*—With the astatic galvanometer between 1 in 310,000,000 and 344,444,444 parts.

4. *Zinc and Platinum with Chlorine.*—With the astatic galvanometer between 1 in 1,264,000,000 and 1,300,000,000 parts.

5. *Magnesium and Platinum with Chlorine.*—With the astatic galvanometer between 1 in 17,000,000,000 and 17,612,000,000 parts; and with the reflecting one between 1 in 27,062,000,000 and 32,291,000,000 parts of water.

Every different soluble substance requires a different proportion, and with unlike substances the difference of proportion is extremely great. With solutions of neutral salts the proportion of substance required to upset the balance is large; for instance, with chlorate of potash, a zinc platinum couple and the astatic galvanometer, it lay between 1 part in 221 and 258 parts of water.

By first bringing the balance with a magnesium-platinum couple and the astatic galvanometer nearly to the upsetting point, by adding 1 part of chlorine to 17,612 million parts of water, and then increasing the proportion to 1 in 17,000 millions, the influence of the difference, or of 1 part in 500,000 millions, was distinctly detected.

HIGH AND SLOW SPEED ENGINES.*

BY J. A. POWERS, C.E.

The able Paper read at the late Convention of the National Electric Light Association, at Pittsburg, by Mr. Wm. Lee Church (see *The Electrician*, 16th March, 1888), suggests some points in the relative coal economy of high and slow speed engines which it is believed are not fully nor fairly treated in that Paper. That the experience of Mr. Church in the making, testing and using of high-speed engines leads him to the conclusion that the independent high-speed engine is the best in average coal economy in incandescent light stations, because the stations which he cites as users of large engines are less economical of coal than other well-designed stations using high-speed engines, is no proof that high speed is a better economist than slow speed, even for the variable loads of incandescent light stations. The great variety of boilers, settings, and draft appliances, and in the quality of fuel in use render any comparisons of coal consumption valueless except as a general index of possible results. The only fair way to state the general problem is to make a distribution of the steam consumption, which would be about as follows :—

* From the *New York Electrical Engineer* of July, 1888.

Digitized by Google

First.—Steam loss by radiation, and used for boiler feed and in providing water supply, &c. This will constitute a certain nearly uniform amount per day for any given plant when under steam.

Second.—Steam consumed in engines, as shown by indicator cards. It is this second item with which we are concerned, as the first will be an individual factor for each station.

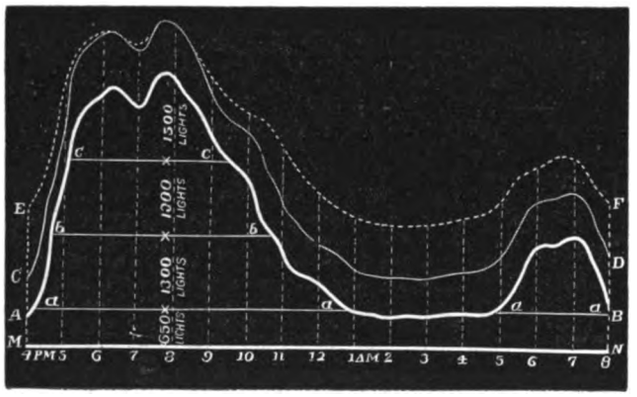
We should then consider the nature of the loads imposed on the power plant in every electric light station, and then deal fairly with the problem. These loads are :—

1st. Friction.—*a*, consists of friction of engines in use ; *b*, friction of shafting in use ; *c*, friction of dynamos and belting in use.

2nd. Effective load ; power required for conversion from mechanical to electrical energy, including the losses in conversion out-put.

It will be evident that the "friction" load in the case of independent engines will be a nearly uniform percentage of the electrical out-put at any time, providing each engine is loaded to about its fair capacity, while in the case of slow-speed engines there will be a certain constant quantity introduced, viz., the friction of the engine shafting and dynamos necessary to be run whether without load or not when dynamos are in operation. This is a consequence of the inflexibility of the shafting system, and we must, therefore, under light loads pay a penalty of a larger percentage of friction to load, than with independent engines, and this will entail an extra coal expense. The question of the coal economy of the two systems therefore depends on whether the slow speed can save enough coal when under heavy load to more than counterbalance the losses by friction under light load.

It is not to be presumed that any sane man will design a station for such a loading as Mr. Church shows in his diagram, which is reproduced below, to be run by a single engine large enough



Mr. Church's Diagram.

(See *Electrician*, March 16, p. 513.)

to handle the entire load. No steam engineer would consider the idea of handling the lightest loads—say from 60 to 75 horse-power—with an engine of 400-horse capacity. The necessities of any but the smallest station call for a divided engine plant. If the question of reserve power be left out, a station of 400 horse might be properly provided with one engine of 100 horse and one of perhaps 300 horse, both slow speed if desired. If the smaller engine be a high-speed the station will be on the same terms as a station with exclusively high-speed engines during the hours of light loading, which would limit the question of relative coal economy to the hours of heavy loading, say from 4 till 11 p.m. and 5 to 8 p.m. The arrangement for such a plant should be to drive each engine to a section of shafting conveniently arranged to give each engine its separate shaft and dynamos. These sections may be coupled by a friction clutch when desired, and friction clutch pulleys should be used for the driven pulleys from the engines. The dynamos may be provided with loose pulleys on the shaft or with some kind of belt holder to enable the dynamo to be stopped without interfering with the line shaft. The dynamos may be belted in opposite directions in pairs when space will permit, so as to reduce friction to a minimum.

Now, in comparing the relative friction of the two systems the friction of dynamos may be neglected, since any dynamo may be stopped as soon as its load is taken off, in either system ; in one case by stopping an engine, in the other by shifting a belt. This brings the question of friction down to whether the friction of large engines and shafting exceeds that of small engines alone.

The friction of high-speed engines is variously stated by engine builders at from five to eight or 10 per cent of full load. Probably the latter figure is not far from the truth, and if it were too large a percentage for full loading it must be remembered that a minute subdivision of power would be required to bring this about, and that this is neither practical in cost of investment nor of operation, and that a reasonably divided power plant will not ensure high-speed engines always working on full loads. The percentage of friction will be greater under less than full loading, since engine friction seems to be nearly constant for all loading in well-designed engines.

Mr. Church states that shafting and engine friction ranges from 12 to 20 per cent. upward, and not infrequently rises to 30 per cent. This may be possible, but it certainly is not so in all cases, and if we allow the same skill in designing a slow-speed station, which some of Mr. Church's show, it is entirely unnecessary. Indicator diagrams from a 20 by 48 Corliss engine, driving 16ft. of $3\frac{7}{8}$ shafting at 320 revolutions, one 50-light Thomson-Houston 1,200 candle-power and one United States 20 arc light dynamo, out of circuit, showed a total of $14\frac{6}{10}$ horse-power, and deducting 3 horse-power for the dynamos this leaves $11\frac{6}{10}$ horse-power for friction of engine and line shaft, or $5\frac{8}{10}$ per cent. if the engine be rated at 200 horse-power. This would indicate the engine friction to be as low as three per cent. The same engine driving 17ft. of $4\frac{7}{8}$, and 33ft. of $3\frac{7}{8}$ shafting with pulleys, but without belts, showed $22\frac{1}{2}$ horse-power, or 9 per cent., for engine and shafting. If the dynamos are belted in pairs with belts pulling against each other there will be no increase of their friction under load. A slight increase under load may be expected from the extra strain of the main engine belts under load, but a fair outside limit of 10 per cent. for engine and shafting friction may be taken from these data.

Now, in the diagram shown of the load of an incandescent station (reproduced above) Mr. Church says that the heavy lines A B represent the fluctuation of the *actual load*, such as would be determined by indicating a series of independent engines, and the area enclosed between it and the base line M N may be denominated the net power required. This presumably includes the engine, belting, and dynamo friction of the high-

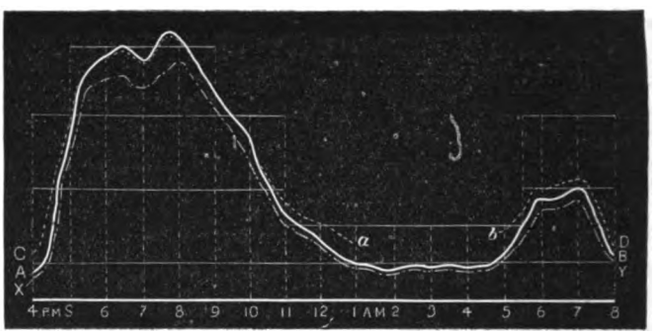


Diagram A.

speed engine. Then Mr. Church proceeds to saddle all the sins of the high-speed system on the slow-speed system by saying :—"The fine irregular line C D encloses the gross load when driven by a single large engine, being equivalent to the *net load* plus the friction of the shafting and pulleys required in transmission," thus assuming that the net load is the *indicated horse-power* of the high-speed engines, entirely ignoring the frictions which are chargeable to that system.

Now let us take some liberties with Mr. Church's diagram (*see* diagram A). We have reproduced his heavy line, A B, of gross loading, as shown by the indicator on the high-speed engine plant. From this line is constructed a new curve, shown in broken and dotted line, which is obtained by deducting from the ordinates to the curve, A B, the 10 per cent. of friction chargeable to the high-speed system. This new line, X Y, is the true line of net power, and it is from this line that we must construct our friction curve for the slow-speed system. This curve, C D, will be found by laying off a line above the curve X Y, and distant from it 10 per cent. of the maximum power in use. The diagram now shows simply the power used in driving the entire station, and does not consider the coal economy of the engines, which in Mr. Church's diagram is charged up against the slow-speed system in the curve E F, and is not considered in the high-speed curves at all. It will be noticed that this slow-speed power curve, C D, nearly coincides with the gross power curve A B of the high-speed system during the times of heavy loads, and that it rises above it as the load becomes less. The station is supposed to be operated by starting the 300 horse-power engine at 4 p.m., and supplementing it with the 100 horse-power at 5 p.m., then dropping off the 100 horse-power at 9 p.m., and starting it again at 11 p.m., shutting down the large engine at the same time. At 5:30 a.m. the 300 horse-power would be started and run till 8 p.m., the 100 horse-power going out of service at 5:30 a.m.

We have now to consider the steam economy of the various types of engines in order that we may discuss intelligently the

Digitized by Google

relative economy of the two systems. The following is a summary of the statement of engine builders on the point :—

	lbs. steam per horse-power-hour.
High-speed engines of 50 to 100 horse-power	28 to 32lbs.
Corliss engines of 200 to 400 horse-power—	
Single cylinder, high pressure.....	24 to 26lbs.
,, ,, condensing	20 to 21lbs.
Compound condensing	15 to 16lbs.

These results would give with an evaporation of eight pounds of water per pound of coal :—

	Coal per horse-power-hour.
High speed	3·50 to 4·00lbs.
Corliss single cylinder, high pressure	3·00 to 3·25lbs.
,, ,, ,, condensing	2·50 to 2·62lbs.
,, Compound condensing	1·87 to 2·00lbs.

These results do not vary much from good practice for the Corliss engines, but the departure is very wide from the ordinary results in the case of the high-speed type. A central station operator of great experience informed the writer not long since that he allowed six pounds of coal per arc lamp per hour as an average result. This would not be less than six to seven pounds of coal per horse-power hour for engines of 50 horse-power. The experience of the writer goes to prove that this result is about correct for engines of that size. For 100 horse-power engines a result, perhaps, one pound better can be had. The results recently shown in changing some stations from high to slow speed seem to indicate the correctness of these results, one such reporting a saving of 50 per cent. in fuel. Another case where a 20 by 48 Corliss was substituted for three 50 horse-power high-speed the results were fully as good, though the Corliss engine was a part of the time under a very light load. The most curious result is that this engine is sometimes run under a load of 125 horse-power during a dark day in place of the 50 horse-power engine which ordinarily carries a day-load of 60 horse-power, and actually carries the heavier load with the same coal, though the Corliss engine works at only half-load, while the 50 horse-power was but slightly overloaded, and at a comparatively economical point of cut-off. This is a comparison of much value in considering the relative merits of the two systems, since the indications are that the Corliss engine is more economical even when under half-loading than the 50 horse-power high-speed engine is at a fair load.

Now let us consider the comparative coal consumption of the two systems on the power curves we have laid out in diagram A. The planimeter shows between the base line and the power lines—

A B	horse-power-hours 3,300
C D	
4 to 11 p.m.....	
11 p.m to 5 a.m.....	
5 a.m. to 8 a.m.	3,580

If these quantities are multiplied by the proper coal rates we have :—

High speed A B, 3,300 × 5lb.	=16,500
Slow speed C D.	
High pressure	3,300 × 3·25 = 10,750
Condensing	3,300 × 2·62 = 8,646
Compound condensing.....	3,300 × 2·00 = 6,600

These results show savings as follows :—

	Saving.
High-pressure Corliss.....	5,750lb.
Condensing	7,854 ,,
Compound condensing	9,900 ,,

over the high-speed engines at 5lb. coal per horse-power per hour.

Now the Corliss engine will not, of course, be working on an economical loading during part of the time, but in order to get an extreme comparison let us suppose that the Corliss system is run at full power whenever in use at all, or, other words, that the coal consumption is the same whether the engine is partly or fully loaded. I do not believe that the most ardent advocate of the high-speed system will claim that the Corliss engine will burn more coal under light load than when fully loaded.

The schedule as above indicated would give the following horse-power-hours :—

310 horse-power, 4 to 11 p.m.	2,170
5:30 to 8 a.m.	776
125 horse-power, 5 p.m. to 9 p.m.	500
11 p.m. to 5:30 a.m.	812
	4,257

which would give the coal consumption—

High-speed at 5lb. coal per horse-power-hour	=16,500
Corliss, high pressure	4,257 × 3·25 = 14,835
,, condensing	4,257 × 2·62 = 11,153
,, comp. condensing	4,257 × 2·00 = 8,514

So that the high-pressure Corliss engine is the better on coal consumption, even under the *reductio ad absurdum* that there is no saving in coal as the load becomes less, and giving the high-speed engine the benefit of a coal rating at full load. It will be noticed also that the coal rates taken for Corliss engines, as above, are the largest rates shown by ordinary practice, and make no allowance for expert care which has its effect on all engines in saving of leakage and friction.

This discussion leads us to about the following conclusions as to the coal economy of the various types of engines, taking the high-speed engine as unit :—

	Coal consumption, lbs.	Percentage, saving.
High speed	16,000	0·00
Corliss, high-pressure	11,000	·31$\frac{2}{16}$
,, condensing	9,000	·43$\frac{8}{16}$
,, comp. condensing	7,000	·57$\frac{2}{16}$

This is believed to be as fair a statement as can be shown from the average practice. These results speak for themselves. We must use condensing engines wherever possible, and to do this we must locate near a plentiful supply of water. If no stream or pond is convenient we must try driven or artesian wells. Both have proved effective, and location must determine the choice. The saving by condensing is not less than 25 per cent. under full loads, and one-quarter of our coal bill will pay large interest on any reasonable expenditure to obtain water supply.

First cost of steam plant is a matter of importance in station construction, and may be fairly stated about as follows for the different types of engines :—

One 100 horse-power engine, high-speed	$1,500 to $1,800
,, 200 ,, Corliss ,, ...	4,500 ,, 5,000
,, ,, ,, ,, condensing	5,200 ,, 5,800
,, 350 ,, ,, comp. condensing	13,000 ,, 14,000

If we add shafting to the cost of the last three engines we shall have a cost per horse-power :—

	Cost per horse-power.
100 horse-power high-speed engine.....	$15 to $18
200 ,, Corliss high pressure	30 ,, 32
200 ,, ,, condensing.....	33 ,, 36
350 ,, ,, comp. condensing.....	45 ,, 48

This is as far as the high-speed advocate usually goes, but it is not far enough. If we need less steam we require less boiler capacity, and this reduction will be nearly in proportion to the coal rates of the different types of engines. A well-set boiler of 60in. diameter by 17ft. long, with good draft, will supply steam for three 50 horse-power engines, but will need forcing to do it. The same boiler will supply a 20 by 48 Corliss condensing engine of 250 horse-power much more easily.

We may fairly state the cost of steel boilers well set, as required by the different systems, about as follows :—

100 horse-power high speed.....	$16 to $18 per h.-p.
200 ,, Corliss	12 ,, 14 ,, ,,
200 ,, ,, condensing	10 ,, 12 ,, ,,
350 ,, ,, comp. condensing	7 ,, 9 ,, ,,

So that the total cost of steam plant will be about as follows :—

High-speed.....	$31 to $36 per horse-power.
Corliss.....	42 ,, 46 ,, ,,
,, condensing.....	43 ,, 48 ,, ,,
,, comp. condensing.....	52 ,, 57 ,, ,,

Now let us compare our results of first cost and saving together.

	Cost per cent.	Coal consumption, per cent.
High-speed	$1.00	100
Corliss	1.31	62
,, condensing.....	1.36	56
,, comp. condensing.....	1.62	44

and with coal at $3 per ton on the above schedule and interest at 6 per cent., the results will be for the 400 horse-power station under consideration :—

	Cost of coal per day.	Saving in coal over high speed.	Interest per day on 400 horse-power.	Loss in interest.
High speed.....	$24.75	0·00	2·36	...
Corliss horse-power	18.90	5·85	3 08	·72
,, condensing	15.24	9·51	3·15	·79
,, comp. condensing...	11.64	13·11	3·75	1·39

Or in a 400 horse-power station the high-pressure Corliss engine beats the high-speed system $5.13 per day, Corliss condensing $8·72, Corliss compound condensing $11.72.

It may be said that these figures are theoretical to some extent; but they will be found to agree pretty closely with the results of good practice for both systems.

It is to be noted that a number of stations lately laid out contemplate the use of Corliss engines, in part at least; and some of them from the plans of the best engineers we have.

The writer hopes to supplement this Paper with a statement of some accurate tests on engines of each type at an early date.

INCANDESCENT LAMP LITIGATION.

Now that the prolonged and exhaustive investigation into the merits of EDISON as an inventor of the incandescent lamp has at last come to an end, and judgment has been pronounced invalidating the patent, the strongest impression left upon our minds is one of utter astonishment that a stringent monopoly should have been maintained so long and so successfully upon a patent of so flimsy a character. "Flimsy," we think, is not too strong—or rather too weak—a word to describe a patent which has been declared invalid on points so fundamental and so numerous as the following:—Because it does not describe a lamp which ever became commercially successful; because the directions were so insufficient that no one could make the carbons described without previous experiment; because one of the processes set forth is positively injurious, and the clauses relating to coated and coiled filaments are of no practical utility; and, lastly, because the claim for a monopoly of incandescent lamps having a filament of carbon is far too wide, "considering," as his lordship added, "how little EDISON has actually invented." We believe that no unprejudiced person who has followed the proceedings can fail to admit that the weight of the evidence demanded this decision, and we must now recognise the fact that the claims of EDISON to be regarded as a discoverer of any element of the first importance in incandescent lamp manufacture are thereby finally exploded. And yet this patent had already stood the test of an action which was carried through every legal tribunal up to the House of Lords! And on the strength of that decision the Edison-Swan Company has extinguished all competition in this country save that of the defendants in the recent action, while the glory of the American "inventor" has outshone that of SWAN or LANE-FOX a hundredfold. We do not, of course, attach any vestige of blame to the company for taking every advantage of their success in the action against WOODHOUSE and RAWSON, but at the same time it is evident that a grave injustice has been done, not only to the firm last mentioned and to other manufacturers of lamps, but to the whole electric lighting industry, to say nothing of the consumers themselves, who have undoubtedly paid many thousands of pounds in virtue of this monopoly. How it came to pass that the Woodhouse and Rawson action resulted as it did is less extraordinary when we remember that no evidence was tendered as to the difficulty of carrying out Edison's specification in its literal interpretation, that no question was raised as to the utility of any part of the patent, and that the

Digitized by Google

historical evidence was of the most meagre description. Mr. JUSTICE KAY, commenting upon the decision of the Court of Appeal, expressly stated his belief that had the same evidence been brought forward on that occasion the learned Judges would have arrived at the same conclusion as he had now done. It is now, however, possible to assert without fear of contradiction, that EDISON did not invent the incandescent lamp. For ourselves, we have never supposed that he did; but there are many people, mostly untechnical, who imagine that he was the true inventor. Even among the electrical fraternity, EDISON, as an inventor, has been somewhat over-estimated. One reason for this is that he possesses the valuable faculty of covering a great deal of ground. If you ask an electric light engineer what EDISON has actually invented, he says, "Oh, nothing much in our line, but look what he has done in telephones!" The telephonist says, "Of course he has not really done anything to speak of in telephones, but he invented nearly everything in the electric light." Then the American Press treat him as a sort of wizard, and his name has gradually become something to conjure with, even in this sober country.

We do not deny EDISON himself, as well as the organisation of clever assistants of whom he is the figure-head, the credit for a vast deal of ingenuity, but we decline altogether to look up to him as the greatest inventor of the age. From our previous knowledge of the subject, aided by what has come to light in the recent trial, we are compelled to recognise that EDISON took a false position in the matter of the incandescent lamp. He knew that high resistance was needed for parallel distribution at the time that he was working at a platinum lamp. In an American patent suit it has come out that in 1878 lamps with paper carbons were shown publicly. EDISON'S people for certain, and perhaps EDISON himself, though that is more doubtful, saw these lamps. EDISON then tried some rough experiments to see if he could get high enough resistance by using paper carbons, and, finding that the results showed some degree of promise, he lost no time in taking out a vague patent, by which he hoped to cover high-resistance carbon lamps, in case they should ever become practicable. On this he poses as the inventor of the incandescent lamp. As anyone who introduces a foreign manufacture previously unknown in this country is entitled to a patent, this would not legally invalidate EDISON'S patent. Moreover, it is very difficult to bring evidence of this character before the Court.

We will now briefly run through EDISON'S specification with the additional light thrown on it during the trial. The object is not to produce a commercial lamp generally, but to make one with a resistance high enough for parallel distribution. He had already described the notorious platinum lamp as suitable, and now, as shown clearly by the provisional, he proposes to substitute carbon for platinum in this lamp, and that is all. He had no doubt found that Sawyer-Man low-resistance lamps contained carbon, and he thought that substance might still do when cut thin. To avoid undue thinness and resulting fragility, and still to get high enough resistance, he coils his carbon into a close spiral. Instead of wanting a very thin carbon he wanted it as thick as he could get it consistently with small radiating surface and high resistance. It was some time afterwards that EDISON "discovered," to use his own expression, that this coiling was unnecessary, so he took out an additional patent for doing without a coiled fibre. The whole of the 1879 specification, therefore, refers to coiled carbons.

The invention further consists in using a good vacuum. The necessity for this was of course well known long before. The method of mounting with tar-putty is the next part of the invention. There is really nothing especially valuable in this, but it is actually the only trace of originality or novelty in the whole specification. Every other suggestion is either useless or well known. So the Edison-Swan Company has had a monopoly of lamp manufacture on a patent whose only merit is a suggestion to mount with tar-putty, a material which has not come into actual use. EDISON'S description of the state of knowledge is quite erroneous. He seems scarcely to know what other people have done since somewhere about the year 1850.

The patent then goes on to say that he has "discovered" that a properly carbonised cotton thread gives from one to five hundred ohms resistance, and is absolutely stable at very high temperatures. After this astounding statement he says that any fibrous vegetable substance which will leave a carbon residue on heating in a closed chamber will do. No doubt an Edison lamp, made under this specification, of spring rhubarb or asparagus would be as valuable commercially as the other forms described. Though fibrous vegetable material includes a great many things, it does not suggest much to a workman. The famous lampblack putty is next described. The manufacture of lampblack putty is an art in itself. The mixture must be kneaded for some hours, and then, with care, you can very nearly make a filament. It is a curious thing that during the whole trial a lamp made with the filament coiled according to the specification was never put in. Apparently it could not be made, even with modern knowledge and experienced manipulation. Various erratic horseshoes and irregular corkscrews were put in, but these were not according to the specification.

In order to get his carbon massive, EDISON introduces camphor or oxide of zinc to keep up the resistance. It need hardly be said that this process is of no practical value. The tar putty mounting is then described, and its object is to allow of mounting before carbonisation, as the filaments are too fragile afterwards.

The inventor once more speaks of the advantage of having his carbons massive. In spite of this it has generally been held that thinness was his aim. He says he has used "cotton and linen thread, woodsplints and paper coiled, and tar putty." No lamp was put into court made with a filament of a coiled wood splint.

He proposes to insulate his coils with some non-carbonisable non-conductor. The drawback to this is that no suitable substance can be found. Every reader probably knows the second and most important claim by heart now. It is, broadly, a claim for incandescent lamps with carbon filaments, and we have briefly shown on what basis it rests.

Apart from this extraordinary patent we cannot find that EDISON has invented anything of real importance in incandescent lamps. Parallel distribution, high resistance to save leads, carbon conductors, good vacua, and hermetical sealing were all well known before his day; parchmentised cellulose was introduced by LANE-FOX; running on the pumps was invented by SWAN or STEARN, though EDISON had stumbled across something of the sort, but had not adopted it; external heating on the pumps was applied to lamps by STEARN; thickened ends for mounting were invented by LANE-FOX, and flashing was also independently devised by LANE-FOX, although it has been held to be covered by CHEESBOROUGH'S patent. We cannot avoid the conclusion, therefore, that of all the important advances in lamp-making not one is due to EDISON.

ELECTRICAL TRADES AND THE LONDON CHAMBER OF COMMERCE.

We announced last week that the London Chamber of Commerce had convened a meeting of those of its members who are interested in the electrical trades in order to consider a proposal for the formation of an "Electrical Trades Section." This

Digitized by Google

proposal, as our readers are aware, emanated from the firm of WHEATLEY KIRK, PRICE AND GOULTY, and the suggestion is one which merits the very fullest consideration. At the meeting on Friday last, which was attended by about a dozen members of the Chamber, a Provisional Committee was formed with the object of arranging for a public meeting of the electrical trades, to be held on July 27th, when resolutions will be moved that the London Chamber of Commerce be requested to establish an Electrical Trades Section. It is earnestly to be hoped that this meeting will be attended by everyone who is interested in the commercial aspects of electrical engineering, and that some definite result may be attained. We are not prepared to say that the scheme referred to will fulfil all the expectations at present entertained by its more ardent supporters; but we do feel confident that the movement will not fail to be distinctly conducive to the business interests of electrical engineers. A glance at its Memorandum of Association will show that the LONDON CHAMBER OF COMMERCE is in a position to afford an admirable basis of operation. Its objects are the promotion of the trade, commerce, shipping, and manufactures of London, and of the home, colonial, and foreign trades of the United Kingdom; the collection and dissemination of statistical and other information relating thereto; the promoting, supporting, or opposing legislative measures affecting those interests; the undertaking by arbitration of the settlement of disputes arising out of trade, commerce or manufacture; and generally to combine for the purpose of promoting the aforesaid objects. The various Chambers of Commerce both in England and throughout the world are in close intercommunion; and there is no restriction as to membership in the London Chamber, provincial firms being eligible equally with those in the metropolitan district.

A few words explanatory of the organisation of the association may be useful to our readers. It is governed by a general council selected from the numerous trades which are upon its roll. Of course, the members include a large number of individuals and firms not directly or specially interested in any one trade; but whenever any considerable body of representatives are desirous of associating themselves for the purpose of more effectually dealing with the welfare of a particular trade, they may, with the approval of the Council, form themselves into a Trade Section; and this, again, may be divided into sub-sections. In the case we are considering there would be an Electrical Trade Section, which would most probably subdivide itself into Electric Lighting, Electric Traction, Telephonic and other Sections. The proceedings of the section and its subsidiaries would be entirely in the hands of the members—with this proviso only, that any resolution arrived at involving action on the part of its members as a body must be submitted to the Council, and if approved would then receive the united support of the whole Chamber. This, it will be perceived, is no small advantage to trades which are not powerful enough to fight their own battles unaided; and the electrical trades are confessedly in that condition at present.

Membership of the Chamber by payment of an entrance fee and annual subscription is, of course, a condition of entry to any of the trade sections. But for those who favour the scheme, or may wish to take part in the preliminary proceedings, in order to decide their course of action, it may be mentioned that membership is not necessary until the final stage has been reached. That is to say, a number of names of persons or firms may be submitted as ready to join in the formation of an electrical trade section, but their entry into the Chamber as members need not be made good unless and until the Council agree to the proposition. This fact will, no doubt, be made known, and will facilitate proceedings at the meeting which is announced for Friday next. It may be hoped, too, that the trade jealousies which were the chief cause of the collapse of the original project last autumn will disappear under the more genial auspices of this new departure. We are not predicting that they will; we only assert that they ought. A Chamber of Commerce is a wide enough platform for all; and the system which prevails there is eminently calculated to assuage personal rivalry and trade feuds. The condition which we have mentioned, that all active measures are subject to the approval of the General Trades Council, admirably serves this end; and although at first sight it may appear irksome, it is a perfect guarantee against the undue influence of mere wealth and the tyranny of numerical majorities. On the whole, we are disposed to look favourably on this proposal; it can do no harm to the SOCIETY OF TELEGRAPH-ENGINEERS AND ELECTRICIANS, and it can hardly fail, if carried out, to do some good to the electrical trades of this country.

ON THE TESLA ALTERNATING-CURRENT MOTOR.

BY J. SWINBURNE.

The account of Mr. Tesla's invention has received such attention from the technical press, and appears to have satisfied so many people that the problem of alternating-current motors is solved, that a short investigation of the subject may not be amiss.

The problem of alternating-current motors may be divided into two distinct parts—to make a motor that will start, and to make a motor that will work with varying loads, preferably with constant or nearly constant speeds, but certainly with reasonably high efficiency in each case. As those who are accustomed to the usual way of treating dynamo problems will perhaps find a little difficulty in following Mr. Tesla's description, an attempt will be made to describe his apparatus another way.

Suppose an alternating-current dynamo, such, for instance, as the Westinghouse, were taken, the armature has, roughly speaking, only half its periphery covered with wire. If another circuit were wound on, filling up the air spaces, it would also give an alternating current if it had its own collectors, but this alternating current would be a quarter of a period behind the other. The same effect would be got by rigidly coupling two alternate-current machines together so that one is a quarter of a period in advance of the other—that is to say, one has its coils in a maximum field when the others are in their minimum field. The simplest form of such a motor would be an ordinary drum armature wound with two coils at right angles, each coil having its own pair of collector rings. This is the example taken by Mr. Tesla. The magnets, of course, are supposed to embrace a quadrant each, instead of about 150 degrees as is usual in continuous-current machines. For simplicity we will suppose the generator to be made up of two ordinary alternating-current machines, coupled rigidly together as described, with two pairs of conductors, each with its own alternating current, these currents differing by a quarter of a period. If a motor is made up in a similar way by coupling two alternate-current machines together, if once started it will run in exactly the same way as an ordinary alternating-current motor, having all its advantages and disadvantages, with the addition that it needs two sets of leads and a special generator. Its efficiency is the same as an ordinary motor, and it will synchronise in the same way. Of course it will not start.

Suppose now that the alternating motor is varied in construction so that the armatures are stationary, the effect will be just the same. A synchronising motor will be obtained which is not self-starting. Instead of this Mr. Tesla uses what he calls a fixed field-magnet with a rotating field and rotating armature in his motor, but we may perfectly correctly call it a fixed armature and rotating field-magnet. The armature is outside the field-magnet, and may be looked upon as a Gramme ring wound with four coils, the opposite coils being pairs, so that there are two circuits. One is connected to each pair of

Digitized by Google

leads. The direction of magnetisation is thus made to revolve just as in any alternate or direct current machines in which the armature is fixed and the field revolves, such, for instance, as the Ayrton and Perry motor or new Siemens dynamo. So far the only result is no better than can be got from machines already known.

As to the exceedingly ingenious method of starting, suppose in an ordinary dynamo an armature is revolved, having some short-circuited coils, the armature resists the motion owing to the currents induced. The armature is revolving, and the direction of magnetisation is fixed; but, as motion is relative, we may say that the direction of the magnetisation and the closed coils are moving relatively to each other. This relative motion is opposed by the currents induced in the coils. Now, if Mr. Tesla winds some closed coils on what he calls his armature, and what is here called his field-magnet, when the direction of magnetisation moves round relatively to the closed coils, currents are induced which tend to make the field-magnet revolve.

This ingenious method of making it start is the only advantage Mr. Tesla's motor possesses. In the synchronising form the closed coils of the field-magnets are used till the proper speed is attained, when the machine falls into step, and the exciting current is switched on, so that they become the field-magnet coils in the ordinary sense. In another form the whole motive power is supplied by these closed coils, so that the machine does not actually synchronise, but goes slower at heavy loads.

Taking the first form, or synchronising motor, we get a self-starting motor, but it needs an exciter, and needs also a special dynamo to drive it, with two circuits, involving three or four leads. In the second form the revolving part cannot be so well described as the field-magnet, because it is excited entirely by the armature. Of course an ordinary direct-current dynamo will work as a motor without any field current if the brushes are put forward, the field being then excited by the armature current; but to make such an arrangement efficient, apart from the question of sparking, which does not now concern us, the armature would have to be designed so as to magnetise the field strongly. In Mr. Tesla's arrangement this is impossible unless the machines are of enormous size. This difficulty would be lessened by making both the fixed and revolving parts on the Pacinotti principle. Instead of using two closed coils on a smooth core, there would also be an advantage in simply encasing the armature in solid copper.

The low efficiency is not at all the chief objection to the scheme. The whole arrangement is unpractical, as it demands special alternate-current generators and leads. There are several ways of starting alternate-current motors. The exciter may have laminated field-magnets, and may be put on the alternate-current circuit to get up the speed, as already proposed by the writer, or a small secondary battery may be used in connection with the exciter, which will start the whole system. It would never be worth while to put down special dynamos and special leads just to use a motor that will start, and that has no other advantages. The two circuits would be useless for other purposes. The transformer proposed by Mr. Tesla must be very inefficient. It has consequent poles revolving, and has thus an open magnetic circuit. It would be better to use the two alternating currents separately, putting some of the transformers on one circuit and some on the other; but if two circuits are to be used it would certainly be cheaper to use a direct current for the motors, and have them self-starting, self-regulating, and efficient. Until Mr. Tesla can produce a motor which will work on alternate-current circuits as they are, and do that efficiently even with varying loads, and without difficulty in starting, he can hardly be said to have solved the problem. With the ingenuity he has already shown no doubt he will do it soon, but he cannot be said to have done it yet.

RE LUTHER HANSON.—Last week a meeting of the creditors of Luther Hanson, electrical engineer, Halifax, was held at the offices of the Official Receiver. The debtor's statement of affairs showed assets £1,724. 17s. 4d., and liabilities £1,518. 3s. 8d., a surplus of £206. 13s. 8d. In this estimate, however, the works had been taken as a going concern. The debtor was made bankrupt, no offer of composition being made.

THE ANGLO-AMERICAN BRUSH CORPORATION AND THE LAMP QUESTION.

The following circular has this day been issued to the shareholders of the Anglo-American Brush Electric Light Corporation (Limited):—

The Directors have reason to congratulate the shareholders upon the result of the litigation with the Edison-Swan United Electric Light Company (Limited), and take this opportunity of putting before them the facts connected with this important case.

It is doubtless within the knowledge of many of the shareholders that the Edison-Swan Company about a year and a-half since obtained a judgment in their favour against the manufacturing firm of Woodhouse and Rawson upon two patents held by them, viz., that which was considered as the fundamental Edison patent for the general principles involved in the manufacture of incandescence lamps, No. 4,576 of 1879, and that of Sawyer and Man (known as the Cheesborough patent), No. 4,879 of 1878, for a process in the manufacture of carbon for electric lamps. These actions were gained by the Edison Company in the court of first instance, before Mr. Justice Butt, and subsequently in the Court of Appeal.

Following these decisions the Edison-Swan Company commenced a system of intimidation against the users of the Victoria incandescent lamps, rendering it necessary for the Corporation to indemnify all purchasers or users against loss or damage, and to call upon the Edison-Swan Company to withdraw such notice, or to take such action as would justify their procedure.

At the same time, not wishing to involve the corporation in the uncertainty of costly litigation in respect of patents which, as has been stated, had been upheld in the Courts, your Directors offered to pay such a recognition royalty as should not be injurious either to the trade or to the interests of the public, provided that the Edison-Swan Company on their part would recognise also, by payment of a non-prohibitive royalty, the valuable patents of Mr. Lane-Fox, the property of the corporation, which the Edison Company use in their manufacture.

These negotiations, which were initiated and conducted by your directors in the most friendly spirit, and which from every possible point of view were honourable and equitable to all concerned, were rejected, and the prolonged and costly litigation which has just been terminated was forced upon your corporation in defence of their rights, and to protect one of the most vital and important branches of their business.

The action was nominally brought by the Edison-Swan Company against Mr. William Holland, of Albert Palace, who was using, and the Jablochkoff Electric Company, who had supplied, a large number of the corporation's lamps, and to whom the corporation had given indemnities.

Upon the application of the defendants that the Anglo-American Brush Electric Light Corporation should take part in defending the action, opposition in the Courts of Law was raised by the Edison-Swan Company, thus endeavouring to preclude the corporation from justly protecting their own interests by defending the attack made on their lamps, but an order of the Court was obtained enabling them to defend as third parties.

In consequence of the procedure of the Edison-Swan Company, your Directors considered that it was necessary to protect your interests by demanding recognition of the Lane-Fox patent, held by the corporation, and they therefore commenced an action against the Edison-Swan Company for an infringement of two of them. This action will come on in due course, and your Directors, having acted upon the best technical and legal advice, await the result with every confidence.

After an exceptionally exhaustive trial, occupying 22 days, the action resulted on Monday last in a judgment in favour of the corporation upon the main issue, viz., the Edison patent, and in favour of the Edison-Swan Company upon the minor issue of the Cheesborough patent.

The effect of this judgment is to invalidate the Edison patent, thus destroying the claim of the Edison-Swan Company to a monopoly for the carbon filament.

The plaintiffs' Cheesborough patent, under which they claim a special method of preparing the "carbon filament" of incandescent lamps, is upheld, and the corporation (who have always contended that they did not employ the process for the object intended and patended by Sawyer-Man) were held to infringe this patent. This latter decision, however, in no way affects the corporation's right to manufacture incandescent lamps, and they will continue without interruption to make Victoria lamps under their own patents, which are quite independent of any process which can be considered as falling within the scope now given to the Cheesborough patent.

With regard to the costs, those incurred in respect of the Edison patent are to be borne by the Edison-Swan Company upon the higher scale; and those incurred in the minor issue of the Chees-

Digitized by Google

borough patent, which are relatively small, are to be borne by the corporation.

It is quite possible that the Edison-Swan Company may appeal against Mr. Justice Kay's judgment, but your Directors have not the slightest uneasiness as to the result.

By order of the Board,

E. GARCKE, Manager and Secretary.

MESSRS. CROMPTON AND CO'S WORKS AT CHELMSFORD.

On Thursday last week, at the invitation of Messrs. R. E. Crompton and Co., a party of engineers and journalists visited the important electrical engineering works of that firm at Chelmsford. Of much that was interesting to be seen we have only space this week for the following notes :—

In the heavy tool shop, on the ground floor, were several large dynamos in course of construction ; the winding and similar work is all relegated to the first floor. Here we were sorry to miss seeing the biggest armature ever built, which has lately gone down to Milton for working the Cowles process. At present the largest armature in hand is for a 5,000 lighter for the Liverpool Electric Supply Company. It is to run at 720 revolutions per minute, and is built on Messrs. Crompton and Swinburne's very pretty modification of the drum winding, which allows perfect ventilation and greatly facilitates repairs.

Perhaps the most interesting machine in hand was the new Crompton-Swinburne Alternator. Here the armature consists of a large number of thin iron discs strung on a centre spindle ; these are clamped together, and the coils dropped into transverse slots. When the latter are in place the whole armature is wound round with a single layer of iron wire ; the copper being thus completely enclosed in iron, the interpolar space can be made very small. The field-magnets are formed very much in the same style as the armature, but are, of course, solid. It is expected that the machine will give 2,000 volts and 32 amperes at 400 revolutions, or eight times the output of a Westinghouse machine of the same size ; this, however, it is frankly acknowledged is on the supposition that the iron in the armature will remain sufficiently cool.

The second floor is principally devoted to instruments, switches, fittings, &c. ; there we noticed some very much improved forms of the Crompton-Kapp instruments.

Returning to the ground floor, we next saw the large switch-board intended for the central station close to Whitehall Court. The switch-board will deal with some 10,000 amperes, and allow for joining up four of the largest size dynamos and eight batteries of accumulators. In the centre portion of the board are eight very large double-ring contact switches, similar to those shown by Mr. Crompton at the Society of Telegraph-Engineers. On the ammeter board Mr. Crompton is going to measure the current by a method which, though old in the laboratory, is now being applied for the first time on a commercial scale. In each circuit is introduced a large bar of platinoid about 12in. long ; from points near the end of each such bar are fine wires leading to a central switch, so that the ends of any bar can be joined to the terminals of a Deprez-D'Arsonval reflecting galvanometer, and the resistance of the bars being assumed constant, the current is, of course, proportional (approximately) to the deflection.

Passing to one of the yards we saw a model of an electric training gear, which has been applied by Messrs. Crompton to a 38-ton gun for the British Government. Here the traversing and elevating movements are both obtained by one handle movable in two planes, the speed variations and reversals being obtained by shifting the brushes. This is a method apparently much favoured by Messrs. Crompton, as we saw it applied to various other motors for different purposes, and though of course slightly wasteful, since the power varies nearly inversely as the work done, yet no doubt in many cases the perfect control of speed thus obtained counterbalances the loss. We also saw in the pattern shop patterns for an electrical crane. This is to lift a net load of 15cwt. 80ft. per minute ; it also has a travel of 80ft. per minute, and can be slewed at 140ft. per minute. All these motions will be obtained by clutch gears from one motor running at constant speed. Among minor novelties we noticed a new brush, made of fine-wire gauze, which Mr. Crompton has tried and found to answer extremely well.

We may add, in conclusion, that on the way down Mr. Crompton showed us some very interesting photos of one of the boilers which caused so much trouble at the Vienna Theatre installation, and which finally had to be replaced by English-built ones. The photos were taken from the boiler which he had broken up before the experts and others, and showed bad work and negligence of a most deplorable description.

EDISON AND SWAN ELECTRIC LIGHT COMPANY v. HOLLAND AND OTHERS.

JUDGMENT OF MR. JUSTICE KAY.

Judgment herein was delivered on Monday last at the Royal Courts of Justice, Chancery Division.

Mr. JUSTICE KAY said : The plaintiffs sue the defendants for infringing two letters patent, one Edison's patent, No. 4,576, of November 10th, 1879 ; the other Cheesborough's patent, No. 4,847, of 1878, amended by disclaimer of the 12th November, 1884, both patents relating to electric incandescent lamps. The defence was taken up by a third party, the Anglo-American Brush Electric Light Corporation. The validity of both patents is put in issue.

The first thing necessary is to ascertain as accurately as is possible to anyone who has not had the requisite scientific training what was known on the subject at the date of these patents, say in 1879. There are two commonly known systems of electric lighting, the arc and the incandescent system. These patents relate to the latter. The former, dependent upon an actual break in the conducting material occurring at the point where the conductor is cast in the form of a pretty thick pencil, the current leaped over the break in the arc, gradually destroying the carbon, and this arc light gave a very white light, especially at the positive pole. The incandescent system is different. The conducting material in this is continued without any break, or actual interval, but being in part an imperfect conductor, that part becomes heated by its resistance in what is called the passage of the current, and this heating, raised to an intense degree, gives the light now familiar to us in the incandescent lamp.

The material that is now so heated is some form of carbon. It was well known that this was a good material for the purpose, because it was an imperfect conductor—in other words, had a high specific resistance—and that it was essential to use it in a vacuum or in some gas or vapour which did not contain oxygen, otherwise the carbon consumed quickly. Until 1872 when Sprengel's air pump was improved by Mr. Crookes, it was difficult to obtain a vacuum which was complete enough. The consequence was that it was necessary to employ a pencil of carbon to carry it effectively, because there was enough oxygen in the exhausted glass bulb to occasion some consumption of the enclosed carbon, and also enough air to diminish the bulk of the carbon when it became incandescent by frictional action on its heated surface, which Edison in his specification and some of the witnesses have called air-washing. Another difficulty which prevented the use of very slender carbons was the irregularity of the current taken from the dynamo ; it was subject to variation, which at times produced a current stronger than the carbons could bear. This was remedied by the improvements of Gramme and Brush, which were perfected in the year 1878. Two modes of improving the resistance of the carbon were known—one by increasing its length, and the other by the diminution of its thickness, or, to use the more exact language of the witnesses, of its sectional area. It was known that the carbon for an incandescent lamp must be enclosed in a glass bulb, from which the air must be exhausted. Bulbs made entirely of glass had been used and publicly exhibited for this purpose. It was known that molten glass could be made to adhere closely to platinum wires, because the glass prepared for this purpose expands with heat in the same degree as that metal ; and that for this reason, and also because of its properties as a conductor of electricity, the best mode of connecting the carbon within the glass bulbs with the main wire through which the current passes was to unite each end to a thin platinum wire, and to fuse the glass around these wires, so that air should not penetrate the points at which they enter the bulb. It was known that by increasing the electromotive force the main wires bringing the electric current to the lamps might be reduced in size, just (to take an illustration given by Sir Frederick Bramwell) as by increasing the hydraulic pressure in pipes supplying a town with water you are enabled to use smaller pipes, because the water will pass with accelerated velocity. It was known that by using high resistance in the incandescent portion of the lamp smaller leading wires might be employed, and also a greater number of lamps might be illuminated from the same source of electricity by working, as Dr. Hopkinson calls it, in multiple arc or in parallel.

Two systems of using incandescent lamps were known, and it was recognised that when many lamps were to be lighted from one central station and at some distance, the system called the multiple arc or in parallel was best. That may be shortly described as a plan involving the use of one main wire and one return wire, each lamp being supplied with the electric current by a smaller wire from the main leading wire, and returning such portions of the current as it took to the return wire, the main leading wire and the return wire being supposed to be parallel. The other system, which is little employed, was the use of lamps in series. In this case the whole current is sent to each lamp in succession, and accordingly lamps of comparatively low resistance are required.

The desideratum in 1879 was to obtain lamps of high resistance for the multiple arc system which could be made commercially—that is, in large quantities, with reasonable cheapness—and, above all, that they should have durability. Edison, Lane-Fox, Swan and others had been working with this object in the same direction. On the 19th December, 1878, in a lecture given by Swan at Newcastle, he described an experiment for the production of light by passing a current of electricity from a dynamo over a slender rod of carbon enclosed in an exhausted globe. On January 17, 1879, he lectured on the same subject at Sunderland, illustrating his lecture by experiments exhibiting certain electric lamps. On the 4th February, 1879, he again lectured at Newcastle, and he then exhibited the lamp which is marked in this evidence with the exhibit mark F J B 1. It

Digitized by Google

consists of a bulb made entirely of glass, with leading platinum wires sealed into it, and connected with a thin pencil of carbon inside the bulb. This piece of carbon was obtained from Carré, of Paris, and was manufactured by him and shaped before being carbonised. It is $\frac{1}{75}$th of an inch in diameter—that is, considerably thicker than the carbons now used, and being straight, the leading wires are sealed in bulbs at opposite ends. This renders it liable to the defect which is alluded to in the correspondence between Mr. Swan and Mr. Stearn, namely, rupture of the carbon, or its separation from the wires by expansion and contraction under the great heat to which it is exposed. This lamp was exhibited again at Gateshead on the 13th March, 1879, and seems to have been kept lighted for ten to twenty minutes at a time on two or three occasions without injury. I have no evidence how long it would last if continuously used. Swan, in the spring of 1879, ordered from Carré carbons in the shape of a hairpin, a model of which he produced, marked J W S 1. It is practically identical in form with some of the carbons now used in lamps, but with a larger sectional area. Lamps made with this would not have the defect to which I have alluded. He says that probably towards the end of 1879 he made some lamps with these hairpin carbons. They are referred to by Mr. Stearn in a letter dated November 26, 1879, in which Fig. 2 is a sketch of a lamp so mounted. But I do not lay much stress upon this as an anticipation of Edison, for although Heaviside and other witnesses speak of having seen these lamps in 1879, I think the fair result of this evidence is that these were experiments which did not succeed in producing a commercially successful result before Edison's patent. On the 2nd January, 1880, Swan obtained a patent for one of the most valuable inventions connected with the manufacture of incandescent lamps. That was for preparing the carbon by passing the electric current through it, and heating it to incandescence while the bulb was still connected with a Sprengel air pump in action. This is now always done, and the effect is to make the vacuum much more perfect, or rather less liable to be impaired by air or gas coming from the carbon itself when first heated in a vacuum. On the 20th January, 1880, he obtained a patent for a horseshoe strip of cardboard prepared for an incandescent lamp by converting it into a substance like parchment, by treatment with sulphuric acid and then carbonising. On the 27th November he obtained a further patent for the application of this process to cotton thread. This has proved a most valuable invention. It produces a non-structural tough material, said by one of the witnesses to be as hard and stiff as a metallic wire; and this is now largely used for incandescent lamps.

Mr. Edison applied, with the object of producing a lamp of high resistance, his untiring and apparently inexhaustible ingenuity. His specification, which I have to consider, shows, as Sir Frederick Bramwell states, that he was not aware how much was actually then known to electricians like Lane-Fox and Swan; and Edison conceived that he was the first inventor of some lamps in which they seem to have anticipated him. Edison availed himself of the more perfect vacuum obtained by the Sprengel pump, and also of the known principle of increasing the resistance of the carbon by diminishing its sectional area, which had become possible to a much greater degree owing to the perfect Sprengel air pump and the dynamo.

Of the important points raised in the construction of his patent of November 10th, 1879, the most important is the extent of the second claim, whether it includes every lamp of the kind there described, the light giving carbon in which is a filament, or whether it means only lamps with such filaments as are particularly mentioned in the body of the specification. Another point is, first, whether the word "lamp" in that claim does not mean merely the filament of carbon. A third question of construction is whether the carbonisation of the filament is to be effected before or after it is attached to the platinum wire With respect to the sufficiency of the specification it is urged that Edison ought to have defined exactly what was meant by the word "filament," and that his patent for 1879 is void for insufficiency of the specification in this respect, and also because it does not give sufficient directions for carbonising the filaments. None of the modes of making the filaments particularly described it is said are practicable, or at any rate some are not, especially the several modes of making the filaments from a putty composed of lampblack and tar, and from that putty compounded or coated with various substances. Also, if the patent means that the filament is to be carbonised after being attached to the platinum wire, this it is said is impracticable because the platinum wire is thereby made porous and brittle, and could not be sealed to the glass so as to prevent air getting at the point of sealment, or through the pores in the wire.

The proper mode of construing a specification, as laid down by Lord Wensleydale in Neilson *v.* Hartford, is to "hold a fair hand between the patentee and the public, willing to give the patentee on his part the reward of a valuable patent, but taking care to secure to the public, on the other hand, the benefit of that provision which is introduced in the patent for their advantage." This refers to the condition expressed in every patent that the patentee shall particularly describe and ascertain the nature of his invention, and in what manner the same is to be performed. Lord Westbury's exposition of the rules of construction (taken from his judgment in Simpson *v.* Holliday) is somewhat more explicit—"With respect to the rules that govern the construction of specifications," he says, "they are the ordinary rules for the interpretation of written instruments, having regard especially to the fact that the specification must clearly fulfil the obligation imposed on the patentee by the proviso contained in all letters patent, namely, that the grant shall be void if the patentee shall not particularly describe and ascertain the nature of his invention and in what manner the same is to be performed." It is therefore made a settled rule that the specification must be so expressed as to be perfectly intelligible to a workman of ordinary knowledge, and it must follow that if there is any obscurity or ambiguity in the specification which is likely to mislead, this defect ought not to be remedied by any refined or secondary interpretation of the language. "It was contended before me," he says, and the Vice-Chancellor is reported to have said that it has been settled by authority, "that the most liberal construction is to be given to the patent that it will sustain, especially in those cases where the Court is satisfied that the invention is really new and useful." If the words *most liberal construction* are intended to denote some principle of interpretation different from the ordinary rules for the construction of written instruments, I am not aware of any such authority. The Vice-Chancellor is made to say that this *liberal construction* is especially adopted in cases "where the Court is satisfied that the invention is really new and useful; but novelty and utility are necessary for the validity of every patent." There is probably some inaccuracy in the note of the judgment. That case went to the House of Lords. None of the learned lords in any way dissented from the passage I have read. I take from the speech of Lord Chelmsford, then Lord Chancellor, the following passage:—"The construction of a specification, like other written documents, is for the Court. If the terms used require explanation as being terms of art or of scientific views, explanatory evidence must be given, and with this aid the Court proceeds to the office of construction." The particular decision in that case was that a description of a process for producing a purple coloured aniline by mixing it with dry arsenic acid and allowing the mixture to stand for some time, or accelerating the operation by heating, was void, because it could not be done without heating it; and that is described as an alternative process.

With regard to the construction of Edison's patent (No. 4,576) of 1879 I observe, first of all, that the provisional specification begins by stating the necessity that lamps connected in multiple should be employed without main wires of great size, and that it is essential that these lamps should have a high resistance. It is stated that this has been set forth in a previous patent of Edison of the same year, and that lamps of great resistance had been obtained by a long wire of platinum or other metal pyro-insulated, which means coated with an incombustible substance, and coiled so that but a small radiating surface was exposed. Then it is said that the present invention relates to lamps of a similar character, except that the carbon threads and the strips are used in place of metallic wire, and connected with the platinum wire sealed into a bulb exhausted of air. The description of the mode of manufacture is then given, but not so much in detail as in the complete specification.

Turning to that I find that it commences with a short statement that the object of the invention is to produce incandescent lamps of high resistance. Then follow four paragraphs stating in what the invention consists. The first of these is the coiling of the carbon wire or sheets so as to offer great resistance and present but a slight surface for radiation; the next, the placing of such light-giving body of great resistance in a nearly perfect vacuum; the third states that the connecting wires are platinum sealed into the glass; the fourth is the method of manufacturing carbon conductors of high resistance and securing a perfect contact between them and the wires. The specification next states Mr. Edison's view of what had been done up to that time. It is admitted that this is inaccurate in many respects. He appears to have been unaware of the attempts that had been made to do the very thing at which he was aiming, that is to increase the resistance of carbon burners in lamps made of bulbs of glass exhausted of air, and the connecting wires being of platinum sealed into the glass. He seems ignorant that bulbs made entirely of glass had been used, or that they had been exhausted of air so as to form a vacuum. The statement is that theretofore the air had been replaced by gases that did not combine chemically with the carbon. The specification then proceeds to describe several modes of making the carbon burners. I find mentioned:—(1) Cotton thread; (2) any fibrous vegetable substance which will leave a carbon residue after heating in a closed chamber; (3) such fibrous material rubbed with a plastic compound composed of lampblack and tar; (4) carbon filaments made by a combination of tar and lampblack; (5) sometimes a thread rolled within such compound; and (6) sometimes the compound with a volatile powder such as camphor or oxide of zinc worked into it, in which case he says to make the light insensitive to variations of the current a considerable mass of matter should be used. The mode of collection is stated to be moulding the lampblack and tar material round the platinum wires, where they are formed to the carbon, and afterwards carbonising them. Coiling is then described, and it is stated that the inventor has carbonised and used cotton and linen threads, wood splints, paper coiled in various ways, lampblack, plumbago and carbon in various forms mixed with tar and kneaded so that the same may be rolled out into wires of various lengths and diameters, each one wire of a uniform size throughout. There are three drawings, two showing carbons very closely kneaded, one of them being within the bulb; and in each case there are clamps connecting the platinum wire cemented within the carbon with the wires sealed in the bulb. The other filament is a straight piece of the substance which is to be coiled attached to the platinum wire at each end. The figure and description of it in the specification show that the coiling and carbonisation are to take place after such attachment. Then come the claims, which are four in number.

"(1). An electric lamp for giving light by incandescence, consisting of a filament of carbon of high resistance, made as described, and secured by the metallic wire, as set forth. (2). The combination of the carbon and filament within a receiver, made entirely of glass, through which the leading wires are attached, and from which receiver the air is exhausted, for the purposes set forth. (3). A coiled carbon filament or strip, arranged in such a manner that only a portion of the surface of such carbon conductor shall radiate light, as set forth. (4). The method herein described of securing the platina contact wires to the carbon filament, and carbonising of the whole in a closed chamber, substantially as set forth." I do not agree that the word "lamp" in the first claim means only the filament of carbon. The claim is an electric lamp for giving light by incandescence, which the

Digitized by Google

filament alone could not do. The words "consisting of" are inapt, but the wording of the whole specification is exceedingly inaccurate, and this is also an example of such inaccuracy; "containing" would be a better word. I construe this claim to mean lamps such as described, in which the distinguishing features are carbons of high resistance made as described, and secured by metallic wires as set forth. This seems to me to make the meaning of the second claim more clear. Having in the first claimed lamps with carbons, made as described, the inventor proceeds to claim all lamps with the combination described in the second claim. These are (1) the carbon filament, (2) in a receiver made entirely of glass, (3) through which the leading wires pass, (4) and from which the air is exhausted. All these four things Edison, as is apparent in the early part of the specification, supposed that he had invented. I do not think he intends to lay more stress on one than on another of them; in fact, the only one as to which it is possible to say there was any novelty was the carbon in the condition of a filament. I take from "Johnson's Dictionary" the meaning of the word—"a very slender thread." The third claim relates to the coiling, on which great stress is laid in the provisional and in the complete specifications, and the fourth is the mode of attachment of the carbon to the wire. The claims, as I read them, are (2) a combination of four requisites for the lamp, (3 and 4) claims for two of those requisites separately, and (1) claim for particular modes of making and attaching to platinum wires the first item of the combination, namely, the carbon filament. But claim 2 comprehends lamps containing carbon filaments however made, and not only those made in the special words described in the body of the specification and included in claim 1. The defendants construct incandescent lamps with all the four elements of the combination described in Edison's second claim, but the filament made by them is essentially different from anything particularly described in Edison's specification. According to the witness Sellon the filament used by the defendants is made thus:—Cotton wool is dissolved in chloride of zinc, and being slightly heated the result is a viscous semi-liquid substance resembling in appearance a strong solution of gum arabic. This is boiled in the receiver of an air pump to extract all air; then it is forced through a die or small orifice by the pressure of a head of mercury, and the filament so formed is received in a vessel of alcohol, which solidifies in the form of thread. It is then left for a time in another vessel of alcohol, which dissolves all impurities and leaves it a non-structural thread of cellulose in an extremely pure condition. It is dried and carbonised and fitted for use in the lamp. If Edison's patent claimed only lamps with filaments such as those particularly described in the body of his specification, it is obvious that this would be no infringement. In 1879 Edison, so far as appears, never dreamt of making carbon filament in this way, but as I have come to the conclusion that the second claim is wide enough to include any lamp with a carbon filament, however made, the defendants have clearly infringed this claim.

Then comes the serious and important question whether so wide a claim can be supported. I have already pointed out the only item of the combination that had any novelty was the use of the filament or very slender thread of carbon. Edison had managed to use carbons thinner than anyone had used previously. The only advantage of a filament suggested in the specification is in high resistance by reason of its thinness or small sectional area. There was no invention described in this specification of any new principle. The principle of increasing resistance by diminishing the sectional area of the carbon was known and had been published by Lane-Fox and by Swan before November, 1879. Assuming that Edison had been the first successfully to put that principle into practice by the methods described in his specification, did that success entitle him to say no one shall make a lamp with a filament of carbon for the burner but myself? Suppose the claim had been thus worded:—"I have succeeded in making an electric lamp with the carbon burner—say, the 100th of an inch in diameter, which gives a high resistance, and I claim a monopoly of all lamps with carbon burners not thicker than that, however made," could such a claim be supported? That in effect is Edison's second claim. One of the objections made is that the claim ought to have been worded in some such way as I have just suggested in order to make it sufficiently definite; in other words, Edison ought to have indicated the exact boundary between his filament and such a Carré carbon as Swan had successfully used. From the drawings and from the great stress laid upon the coiling of the filament, the only object of which seems to be to increase the resistance by using a considerable length, I should conclude that Mr. Edison did not conceive that extreme thinness of the carbon was practicable. Mr. Swan had tried paper, cardboard, and similar material carbonised, and if he had not tried a filament he had used and obtained considerable success with the Carré carbons not more more than $\frac{1}{250}$th of an inch in diameter. He was trying these in the form of a hairpin, made and shaped to that form before carbonisation, and it seems impossible to say that Edison by reducing the thickness of the horseshoe carbon had made any vast invention or contributed largely to the knowledge that such inventors as Swan and Lane-Fox already had upon the subject. There is authority for saying that if an inventor discovers some new principle and describes a practical mode of applying it he may have a patent which would prevent another person from applying the same principle by different means. In Jupe *v.* Pratt Baron Alderson said:—"You cannot take out a patent for a principle; you may take out a patent for a principle coupled with the mode of carrying the principle into effect, provided you have not only discovered the principle but also invented some mode of carrying the principle into effect. If you have done that, then you are entitled to protect yourself from all other modes of carrying the same principle into effect"—that being treated by the judge as piracy of your own original invention. But is there any decision that an inventor who has discovered a mode of applying a known principle like this of obtaining increased resistance by diminishing the sectional area of the carbon burner can obtain a monopoly of the principle? Sir Frederick Bramwell, in his evidence for the plaintiffs, put the case in the strongest and most favourable manner by saying that Edison made the first commercially successful incandescent lamp. Unless that is so his claim to so large a monopoly would not in my opinion be arguable.

I proceed to inquire, did he make a commercially successful lamp—that is, were any of the modes of making lamps particularly described in the specification commercially successful?

In most patent cases, when the validity of the patent is impeached for want of novelty, the most important witness is the inventor. It is usual to put him in the box and expose him to cross-examination. Mr. Edison is in America, but if there was any reason which prevented his appearing as a witness at the trial, the Court has power to direct an examination in America. He has neither been produced nor has the attempt to examine him in America been made, and an objection was raised during the evidence to reading statements made by him in his later patents to show what he really had invented at and before the date of his patent of 1879. I must say that this mode of conducting the plaintiffs' case seems to me to put the defendants at an unusual disadvantage, and I think the Court is bound to prevent them from being prejudiced by it so far as possible. I shall not hesitate to refer to the language of Edison's subsequent patent as admissions by him, so far as they tell against the claim now made in his name to a large monopoly.

I have before me several patents by Edison in his own or other names. There are, amongst others, three in 1878—Nos. 4,206, 4,502, and 5,306; three in 1879, numbered 2,402 and 4,576 (which is the patent now in question) and subsequently, in 1879, No. 5,127; in 1880, No. 3,765, which has been called in the argument the bamboo filament patent; and in 1881 Nos. 539 and 1,918. Whenever he hit upon any improvement Edison seems to have applied for an English patent, without waiting to perfect the invention, and no one can read the patent in question of 1879 without being struck with the imperfection of the description in every part. In the later patent, No. 5,127, of 1879, Edison gives careful directions as to the mode of carbonising strips of CRYSTAL WIRE in the mode preferably of wrought iron. In the bamboo patent, No. 3,765, of 1880, he begins by again asserting that the practice, so far as he knows, had been to make the carbons of as low resistance as possible, and that he had discovered that the incandescent material should have the highest possible resistance in a very small bulb, and further that the carbons which are purely structural in character and known to possess these qualities—by purely structural he meant the carbon wherein the natural structure, celluloid or otherwise, of the original material is preserved unaltered, that is, it is not modified by any treatment which tends to fill up the cells or pores in structural carbon, or to increase its density or to alter its resistance. One object of this invention, therefore, is to provide such carbons, with means and methods for their manufacture. He then mentions several kinds of vegetable fibre, among others the bard, glossy exterior of the bamboo cane. Elaborate directions are given for shaving and carbonising these fibrous substances, and the claims include (1) an incandescent conductor formed of one or more carbonised natural fibres, (6) a slip or filament made of glass or fibre like cane or bamboo, and (12) the method of forming and then ot carbonising. In all there are in this patent 44 claims. To say that purely structural carbons alone possess the requisite quality was altogether an error. Swan's non-structural carbon, parchment *carbons* it is there called, are amongst the best burners known.

The plaintiffs have been challenged again and again during the cross-examination of their witnesses to prove, if they can, that any lamps with a burner made according to the specification of November, 1879, has been brought into the market in England or in America. No evidence of this has been given, and I conclude that there was no commercial use of the invention at that time. Until he had taken out the subsequent patent it seemed that Edison did not introduce any lamp to the public. Dr. Hopkinson saw some, he says, probably in 1881, made under one of these later patents. In that year—1881—Edison exhibited some at the Paris Exhibition in the month of September. These were bamboo filament lamps, and this was the first public exhibition of his lamps, at any rate in Europe. No doubt this is not conclusive that the invention had no utility, because as it has been argued improved lamps may have been invented so rapidly as to have superseded the original invention before it could be brought out publicly. But it is somewhat difficult to make out that the lamps described in the specification of 1879 were commercially successful if none were ever brought into the market, and the success of a lamp made under a subsequent patent, like the bamboo lamp, which has been largely used, can hardly support the previous patent, which it did not describe. It has been attempted to argue that the patent of 1879 did include the bamboo filament—first, because the second claim includes all filaments of carbon; and, second, because in the body of the specification Edison says, "I have carbonised and used wood splints." I can only say that I admire the courage of such an argument. The question is whether the specification particularly describes a commercially successful lamp so as to support so wide a claim. This is not answered by saying that the claim is wide enough to include all filaments, and therefore it must be taken to include all; and in respect of so much of the argument as rests on the use of the words "wood splints," those words do not describe anything so as to show a workman how to make them. Indeed, they are not intended as a description, for it is a recurring sentence, which may be properly called a passing observation, as though here, as in other parts of the specification, Edison was simply putting on paper cursory allusions to experiments; how made, and whether successful or not, he does not pause to say. But filaments made according to the several descriptions in the specification have been made, carbonised, and used, by way of experiment, in order to show that it was possible to make them.

Upon this there was a considerable conflict of evidence. Mr. Crookes, the celebrated chemist, following the terms of the specification as he un-

Digitized by Google

derstood them, detailed experiments which he had made which failed completely, and declared that he was quite unable to make the carbons successfully from the descriptions given. On the other hand, a young man named Gimingham, who had had some scientific education, was produced as a witness for the plaintiffs, and he deposed that he had from the specification alone, without any special instruction, made carbons successfully without any difficulty. Other witnesses supported Mr. Crookes on the one side and Mr. Gimingham on the other. Some of the reasons for the success of one set of these experiments and the failure of the other were pretty clear; others I could not understand, and at my suggestion the parties agreed that the experiments should be repeated in the presence of Prof. Stokes, whom they chose as an independent expert, who should report the result to the Court. I have that report, which the parties have seen, and it is obvious from it that no one with the knowledge that existed in 1879, unless he was as practised as Mr. Edison himself or Mr. Swan, could have made a successful electric incandescent lamp from Edison's description without a long series of careful experiments and very many failures in his attempts.

With respect to the commercial success of the invention as tested by these experiments, I find from the report and a supplemental table of results, which have been handed to me as an agreed statement, that out of 100 lamps some broke down at once, thirteen lamps lasted less than ten hours, eleven more less than twenty hours, eighteen more less than forty hours, and only six above forty hours, of which four were unbroken at sixty hours, and of these four there is no further record. That is far from commercial success. No system of electric lighting could be maintained (except at an expense which could not practically be incurred) with lamps of such short life as these; and this explains most satisfactorily why Edison never sold lamps made according to the specification of 1879.

In considering the sufficiency of this specification, it must be remembered that in 1879 there was no trade or business of manufacturing electric incandescent lamps. Lane-Fox, Edison, Swan, and other inventors had given much time and attention to the subject; but except such persons there were none who had any special knowledge in the matter. The dicta that may be found in some cases that the specification of certain patents must be read as addressed to adepts in a particular trade or business do not apply. For this reason it was essential that the specification should be carefully explicit; it ought to be such as would enable an intelligent working man to make an incandescent lamp without having to try experiments. Take, for example, the process of carbonising filaments. In his subsequent patents Edison gave elaborate directions for this. In this patent, though dealing with filaments made of a putty compounded of lampblack and tar, common thread, thread coated with the putty, the putty combined with camphor, or oxide of zinc, and other substances for the manufacture of carbon filaments, he contents himself with saying that the cotton thread is to be properly carbonised, the fibrous vegetable substance is to leave a carbon residue after heating in a closed chamber, the tar putty is to be carbonised in a closed chamber by subjecting it to a high heat. Nothing is said to indicate what sort of closed chamber, of what it is to be made, how it is to be used, the degree of heat to be applied, nor the length of time during which the heat is to be kept up. There is no mention of any packing to be used in the chamber, nor of any precaution to prevent distortion of the filaments during carbonisation. There was no industry in 1879 in which carbonisation of anything so small as a filament was used. It was known to chemists that one mode of carbonising was to pack the substance to be carbonised in powdered charcoal, which when heated gradually combined with any oxygen which might be in, or might during the process find its way into the vessel used, and thus the substance to be carbonised might be protected from being consumed. This mode of carbonising is mentioned in the patent of Pulvermacher for making arc carbons before 1879; but this was not generally known, and it is not alluded to in Edison's patent which is now in question. Carbonising filaments in an ordinary clay crucible without such packing will not do; they are consumed, and nothing but ash remains. It seems it can be done in an iron box with a lid carefully luted if the heat be gradually applied and for a short time; but the carbons now used commecially are exposed to furnace heat applied gradually at first and kept up for a period of eleven to 14 hours, and they are carefully packed in powdered charcoal and wound on a frame and dried so as to yield as they contract. I have no reason to suppose that anything like that time or so great a heat could be successfully used with filaments in an iron box without packing. I am satisfied that considerable experiment would have been necessary in 1879 to discover what sort of closed vessel would do, whether packing was necessary, and what amount of heat, and for how long, and how it was to be applied. The specification seems to me altogether insufficient in these respects.

Then as to the tar putty, it seems it may be made by kneading the materials with some exertion for an hour and a-half. The only direction given is that it is to be kneaded till it assumes the consistency of thick putty. I have no reason to doubt Mr. Crookes honestly tried to make it and failed; a workman could not have fared better and could not have succeeded without much experiment. The filament which is to have a volatile powder, like camphor or oxide of zinc, worked into it has been imitated by dusting the tar putty filament with these materials very carefully, but I do not think it has been done in the experiments as Edison had intended. The description is vague, but I conclude from the mention of a volatile powder that the object was to use something that would volatilise in the process of carbonising, and that a considerable mass or thickness of carbon was to be used which would be left by such volatilisation in a very porous condition, and would thus have its resistance increased. The experiments seem to me a mere pretence of carrying out this; no such carbon has been shown to be of any practical utility. Considerable evidence has been given to show that coating the carbon with a non-conducting, non-carbonising substance would cause its destruction and incandescence by decomposition of the coating, the oxygen in which when free would destroy the carbon filament. The evidence leaves it somewhat in doubt whether this occurs before an actual fracture of the carbon occasioning the intense heat of the arc.

I do not think it necessary to observe at length upon other objections that were made on the specification. One of these referred to the effect on the platinum wires of exposing them together with the burners in the process of carbonisation, which, as I have mentioned, the drawing in Fig. 2 and the description of it showed what Edison intended. Another is the using of the copper helix to assist in the coiling of the burner; another is the use of the coil of the carbon, which Edison describes for the purpose of measuring the resistance by length without enlarging the radiating surface in proportion to the length of the barner. This seems to have been abandoned as useless.

My opinion is that the patent of Edison (No. 4,576, of 1879) is invalid; first, because the second claim is for a monopoly of incandescent lamps containing a filament of carbon for a burner, which claim, I think, is far too wide considering how little Edison had actually invented; secondly, because his specification does not describe a lamp which ever became, or, as I think, could have become, commercially successful; thirdly, because the directions therein contained are so insufficient that no one could have made the carbons he describes without considerable previous experiment; fourthly, because one of the processes described, namely, mixing the carbons with volatile powder, I believe to be practically injurious if done as Edison directs; fifthly, because the coating with a non-conducting, non-carbonising substance, if not injurious, is of no practical utility; sixthly, because the same may be said of coiling the filaments, on which the patentee lays great stress.

This patent of Mr. Edison (No. 4,576 of 1879) has been the subject of litigation in a previous suit between the present plaintiffs and Messrs. Woodhouse and Rawson, who were manufacturing incandescent lamps, and were sued by the plaintiffs for infringement. The case went to the Court of Appeal, and both in the court of first instance and in the Court of Appeal the patent was treated as valid, though apparently with some hesitation. I am bound by these decisions, and should follow them of course, whether I agreed with them or not, if the evidence in the two cases were the same. But that is not so.

On one point which Lord Justice Cotton seems to have thought essential the Courts were completely misled; they were given to understand that the carbon burner in the lamp F J B 1 exhibited by Swan before the date of Edison's patent was shaped after and not before carbonisation. It is now admitted that this was not the fact; it was a carbon made by Carré, and used as made by him without alteration. But further I am told there was no evidence in that case as to the difficulty of making the carbons described in Edison's patent from the description in the specification. I understand that no contest took place as to the sufficiency or utility of any part of Edison's patent, and that nothing like the evidence as to the previous knowledge on the subject was given in that trial which has been adduced in this. With respect to the construction of the patent the opinion which I have expressed agrees with that of the majority of the learned judges in the Woodhouse and Rawson trial. The case has been brought before me with such an elaboration of evidence on every point that I think myself bound to act upon my own opinion, believing, as I do, that if the same materials had been before the learned judges in the other case they would have arrived at the same conclusion as I had done.

The other patent in question in this action is that of Cheesborough (No. 4,847) of 1878, amended by disclaimer of the 12th November, 1884. The specification describes and claims a method of preparing the illuminating portion of an electric lamp, and also a material for the manufacturing of the illuminating part. Shortly stated, the carbon to be prepared is surrounded with a carbon gas or liquid, and then heated intensely by the passage of the electric current. This causes a decomposition of the surrounding hydro-carbon, and the deposit upon the heated surface of an extremely dense form of carbon, such deposit being in a greater quantity upon the hotter, that is the thinner, portions. The specification states that the carbon of the ordinary sort when heated by the electric current exhibits points and lines of unequal brilliancy. Carbons prepared by this process when so heated glow with a uniform brilliancy throughout. A French chemist, Deprez, in experimenting on the reduction and volatilisation of carbon, discovered that when the carbon was heated in an atmosphere of hydro-carbon this deposit occurred, and interfered with his operations, and he described this in a Paper which was published in England some years before 1879. But Deprez did not utilise this product in any way, and his experiments had nothing to do with electric lighting. Assuming that Cheesborough derived his knowledge of the mode of producing this material from Deprez's Paper—I believe Cheesborough was not the real inventor?

Sir HORACE DAVEY: No, my lord. Sawyer and Man were the real inventors—he is the English patent agent.

Mr. JUSTICE KAY: Yes, I understand. Assuming that the patentees derive their knowledge of the mode of producing this material from Deprez's patent, their invention consists in applying it to the purpose of making uniform the light-giving power of a piece of carbon when heated by the electric current, and the beauty and the merit of the invention consist in thus enabling an imperfect carbon by a sort of automatic operation to improve and perfect itself. I have no doubt that this is a good subject for a patent. I had more hesitation upon the claim for the material, which certainly was not discovered by him; but that is not the whole of the claim, it is for a material for the manufacture of the illuminating conductors of electric lamps produced by electricity heated in a carbon gas. That does not prevent anyone from making the same material and using it for other purpose. The claim is really for the use of the material for the burner of an electric lamp. This seems to me equally valid. Another objection that pencils cut from the lime cylinder, coated with carbon, would not make effective burners seems to me to arise from a mis-

Digitized by Google

construction of the specification. It is not the lime cylinder, but the deposit of the carbon which is to be made into burners. The defendants have used this process of Cheesborough, but they say for a different purpose. Their object is to bring all their carbons to one standard of illuminating power, an operation for which they have invented a somewhat cacophonious word, "standardising;" but Sellon, one of their principal witnesses, admitted that the process would cure any inequalities of light-giving surface in the particular carbon so treated. These, he says, in their cellulous threads seldom occur. However, I cannot resist the conclusion that the defendants by this use of the process for carbons of incandescent lamps are infringing Cheesborough's patent.

The plaintiff's reply in this case was unfortunately interrupted. The Attorney-General asked leave if the Court required more assistance on any point to add somewhat to the reply. I have not thought it right to trouble him further. Every point has been put again and again to the scientific witnesses; twenty-one of the working days of the Court have been occupied trying this case. I have not arrived at the conclusion I have intimated without considerable thought and care, and I do not think that further argument would be a useful expenditure of public time. I must therefore decline to trouble counsel any more in the case. I have been provided with a copy of the print of the shorthand notes. They contain, as is perhaps inevitable in such a case, a considerable number of verbal inaccuracies, some of which completely distort the meaning of what was said.

The action so far as it relates to Edison's patent of 1879 must be dismissed with costs. There must be an injunction to prevent any further infringement of Cheesborough's patent, and the defendants must pay the costs of the action so far as it relates to them. The costs must be set off in the usual way.

On the application of Sir HORACE DAVEY, in order to comply with the Patent Act Mr. JUSTICE KAY consented to certify that the objections of the defendants were all "reasonable" objections, and in order to allow costs on the higher scale that the case was of sufficient "importance and difficulty."

On the application of Mr. BREMNER a certificate was also granted in the case of the Cheesborough patent giving costs as between solicitor and client.

Mr. ASTON applied for costs on those points of the Edison patent on which the plaintiffs were successful, but the learned judge refused to grant the application.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *July 7th*, 1888.

The dispute regarding overhead wires in this city has arrived at a climax or crisis, and the result is that at least 100 arc-lights will remain unlighted until peace is again restored. A few days ago, becoming somewhat weary of the delays interposed by the local United States Illuminating Company, the Board of Electrical Control addressed to that company a letter notifying it that its wires along certain routes where subways had been provided but had not been used would be operated at the peril of arrest on the part of all engaged in the work. To this, Mr. Lynch, the president, replied that he had been doing his best to get cable to make tests in subways, but had been unable to secure any satisfactory guarantee as to the durability of such cable for the intended purpose. At the same time the company re-asserted its doubts as to the efficiency of the subway system within the meaning of the law. This reply seems to have acted on the Board like a red rag on a bull, as its secretary was immediately instructed to send a reply to the company expressing surprise at its lack of good faith in its relations with the Board, and addressing the company in the following language:—"You will be allowed no longer to operate your conductors in the shiftless, reckless manner heretofore adopted by you, as evidenced by the numerous reports of dangerous places in your lines made by our inspectors day by day, and if you are quite right in your assumption that your business cannot be done according to the directions given you by this Board, then you must distinctly understand that you will not be allowed to do business at all in this city of New York." The company is told, too, that its objections are "specious, calculated to deceive, not founded on fact, impertinent to the issue, and in opposition and evasion of the laws of the State." When such polite phraseology is used it will be seen that the situation is critical, and it need not be wondered at that, rather than proceed to extremities at the present, the company decided to discontinue operating its lines in the districts named by the Board until the question had been definitely disposed of in a court of law. In view of the undoubted fact that public sympathy and opinion is with the Board in this subway fight, and that the Board has been vested with very full powers by the State, it is evidently the best policy for the company to find a *modus vivendi* under the new conditions, as the other companies appear to be doing. At the same time there are certain points to be considered on the company's side. The subways themselves are anything but what they should be, and in many instances are reported to be full of water. Moreover, no provision has yet been made for local distribution, as the manholes are placed only at the ends of each block. In case a subsidiary conduit should be built, the company will be charged $1,000 a mile per year per duct. The cost of the whole conduit is said to be only $4,000 per mile, an outlay which makes the rent seem outrageously high. Another point is that legal proceedings to test the right and power of the Board in this matter had already been initiated. In the meantime, the mayor had himself expressed the opinion that the commissioners could not compel the electric companies to put their wires into the subway until they had adequately provided for local distribution.

As an appendix to the above, which outlines, as I have said, a very serious condition of affairs, it may be added that Prof. W. A. Anthony, at a meeting of the New York Electric Club, held last week, presented a Paper on overhead wires, in which he took the ground that the dangers of overhead wires had been greatly exaggerated, while the difficulties of placing the wires underground had been not less unfairly minimised. He pointed out how few were the number of deaths from contact with the electric light wires, and then contrasted their number with the fatalities daily reported in connection with other city conveniences, such as horse cars, carriages, and the like. As Prof. Anthony pointed out, the danger from overhead wires is by far the least of all the reasons for removing them.

It is interesting to note the fact that a new electric art makes its bow to the public this week. The Thomson Electric Welding Company of Boston has just issued a very handsome pamphlet, giving details as to the apparatus which it has built for the purpose of putting into commercial operation Prof. Elihu Thomson's process of electric welding. The method, as most of your readers are doubtless aware, consists in causing large currents of electricity to pass through the abutting ends of the metals to be welded, thereby generating heat at the point of contact, which also becomes the point of greatest resistance, while at the same time mechanical pressure is applied to force the parts together. The metal being heated to the welding temperature, and the pressure backing it up, so to speak, the complete weld is effected, and every test made has shown, with every variety of metal, that the interior of the weld is as perfect as the exterior. The machines now being built by the company will handle all kinds of work, from the finest wire to bars over 3in. in diameter, while special machines are made for heavier work, such as shafting, locomotive frames, tubes, &c. In one form of the apparatus a small converter is placed in the base so as to take current from a distant dynamo, at a central station, for example. In the other case the dynamo and the welding apparatus are combined in the one machine, which can be put anywhere in a manufacturing establishment, and be driven directly from an engine or from line shafting. There can be no question that this apparatus is intended for very extensive application, and that use will be found for it immediately in a great many places. As to the patents on which the art is based, they are broad and comprehensive, but it will not surprise you to learn that there are interferences and counter claims.

If I recollect rightly I made brief mention in my last letter of the fact that at Wabash, Ind., tower arc lights had been replaced by incandescents on low poles for the purposes of street illumination. What gives the more interest to this change is the fact that Wabash was one of the first, if not the first, to adopt tower lighting. In the new system which is being put in by the Heisler Company, 132 lights of 30 candle-power each have been dispersed at street intersections on low poles which carry the light about two-thirds of the height, or

Digitized by Google

12ft. from the ground. The same steam plant as was used for the arcs is used for the incandescents, leaving, it is claimed, a very large margin of power available for commercial lighting. It is said that the change has proved satisfactory. I daresay that the results are being watched pretty closely, as should the plan be a continued success it is likely that the tower system would find in it a formidable competitor.

I have just said that tower lighting would find a competitor in this system of low lighting, as it does, for that matter, in the Edison municipal system. It is also likely that gas, too, would find it very often difficult to fight against. One of the arguments in favour of street gas lighting has been that it affords a much better distribution, from having a light every few yards along the street. There is, perhaps, something in this, but as the same can now be said for electricity, the argument, as an exclusive one for gas, vanishes. I notice, by the way, that down South, the number of new electric light companies organised during the past six months was 80, as compared with 33 in the same period of 1887, notwithstanding the fact that the number of new gasworks fell off from 24 to 18. Another indication of the way the wind blows is shown in the remark made by a leading gas journal last week, to the effect that in the city of Boston the electric motors introduced there had diverted from the gas company a patronage that was equal to the consumption of no less than 50,000,000 feet of gas per annum; and it need not be said that the number of electric motors there is very rapidly on the increase.

There are various and conflicting reports as to the phonograph and graphophone, and the most trustworthy of these rumours indicate that the two interests have been combined. So far as can be gathered, the practical basis upon which negotiations have been concluded is that Mr. Edison through certain patent complications, as in other cases in which he has similarly suffered, no longer has the practically absolute control of the phonograph that he once had, and that the phonograph as now built embodies certain very material improvements which have been made and embodied in the graphophone during the last few years by Mr. Tainter, of Washington, one of the associates, I believe, of Prof. A. G. Bell in other lines of work. Such being the case, a company formed as the result of the combination will it is said place the two machines, the phonograph and the graphophone, on the market, under the name of phonograph, and will ultimately, it may be expected, build one machine embodying the best features of the two, as well as other improvements which will inevitably be made. I believe that the "new phonograph," as it is called, has recently been exhibited in England, as it has been here. It is said to be surpassed by the graphophone in many important respects, as to the simplicity, ease of operation, and effectiveness of record.

The July number of the New York *Electrical Engineer*, which is just out, finds in the dilapidated condition of some electric light plants an exact reproduction of the state of affairs which existed in the telegraphic service thirty years ago, and it believes that, as surely as history repeats itself, the same remedy will be applied, namely, the consolidation or union of interests. The parallel hardly seems exact, however, and, as a consequence, the inference, though logical, may be unsound. In the case of the telegraph service, outside connections from city to city are a first and absolute necessity, whereas in the case of a local lighting company all that is necessary is a reasonable local patronage, altogether irrespective of what may be done in a city only a mile away. It might be argued that with a strong combination of parent companies there would be less likelihood of competition among the local companies, which have often been started, not so much because the town wants another plant, as because the company wants another customer. On the other hand, now that the manufacture of dynamos is virtually open to everybody, and when new lamps come out nearly every week, there may be no more reason for combination on the part of the manufacturers of such apparatus than there is on the part of engine builders, whose name to-day is legion. There have been moves made in the direction of a grand consolidation, and the diplomacy employed has been of a very high order. The golden opportunity for such a combination presented itself several years ago, at the time of the old Gramme pool, but it slipped by. To day we have ten builders of electric lighting apparatus where one existed then. There is a good deal of force, however, in the view presented by the *Engineer*, and the situation is an interesting one. It can readily be understood that there would be nothing small about a combination which embraced some thirty or forty manufacturing companies, and at least a thousand local central stations.

I note that the *Electrical Review* (of New York) this week gives some views of Mr. Edison's new laboratory, at Llewellyn Park. This laboratory, which has also a library and a workshop, is one of the finest in the world. It comprises a main building and power room, in which is located a couple of Armington and Sims engines, of 150 horse-power each, driving Edison dynamos, whose current is used for lighting and other purposes. At the rear of the main building are four separate one-story brick structures — the galvanometer house, the chemical laboratory, the pattern room, and the metallurgical building. In the main building considerable space is devoted to the library, which now contains a large number of books, and bids fair to reach 100,000 volumes. Mr. Edison has spared no expense in the equipment of the laboratory, and he has gathered around him a staff of great ability and efficiency.

Last week, Mr. Alfred Shedlock read a Paper before the New York Electrical Society on the "O'Keenan Battery," intended for domestic electric lighting. Possibly some of your readers may be familiar with this battery, as it has come to us from abroad, but to those who are not, a short description may not be out of place. Mr. O'Keenan has simply taken the ordinary gravity type of battery in which zinc and copper sulphate are employed, and has arranged it so as to make it as efficient as possible and automatic in its action. The zinc plates are suspended within porous partitions and flanked on each side with a lead plate. The sulphate of zinc circulates around the zinc plates and settles at the bottom of the vessel within which the plates are placed. Upon this is a layer of the sulphate of copper in contact with the lead plates, and above all is a layer of water. A hopper connected by a slot with the layer of copper solution keeps that solution constantly saturated, while a steady stream of water constantly serves to keep the sulphate of zinc solution at the proper density, the saturated solution making its escape through a trap at the proper time. The copper is deposited on the lead plates, and when of sufficient thickness the lead plates are lifted out and the copper stripped off. Being of the purest quality, this copper can readily be sold at a good price. The battery is usully worked in connection with a set of storage batteries, which it charges continuously, there being two sets of the latter charged in parallel, and discharged in series, so as to obtain an increased E.M.F. for the lighting circuit. Mr. Shedlock stated that the primary battery of this shape, having 12 cells, is adapted to give an available daily supply of electricity of about 126 ampere-hours at 16 volts, or any other number of amperes in proportion; in other words, the battery is able to light fifteen 12 candle-power 3-watt lamps for three and three-quarters of an hour, or a less number of lamps proportionately. The cost of the zinc and the copper sulphate, less the value of the copper deposited, is about 50 cents per day, or at the rate of about one cent per lamp hour.

Telephone Extension to Lancaster.—The Lancashire and Cheshire Telephonic Exchange Company (Limited) have just completed an important extension by connecting Lancaster to their trunk line system. Lancaster hitherto has been one of the very few commercial towns in Lancashire not possessed of telephonic communication with other places, but now they will be able to enjoy this important business facility. The building of the line has been executed with extraordinary despatch by the company, notwithstanding the many difficulties to be met with in carrying their work through a country extending from Blackburn to Lancaster, covering near upon thirty miles. The first delivery of poles and other stores was made at Wilpshire Station on May 18th, and the communication opened to the public on July 13th.

CORRESPONDENCE.

THE LONDON CHAMBER OF COMMERCE AND THE PROPOSED ELECTRICAL TRADES SECTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The subject of forming an association to represent the commercial interests of the electrical industry has been frequently under discussion during the past few years, and there is apparently a consensus of opinion in favour of some kind of organisation being formed to secure united action; but the chief reason why the past attempts to establish such combination have failed is the difficulty of defining the scope and limits of the proposed association.

We all recognise the necessity for combination in matters of common interest, but we are not all agreed as to what our common interests are. This is probably attributable more to the peculiar conditions of the industry in this country than to any fundamental difference of opinion. My object, however, is not to discuss this, but to point out how I think the difficulty referred to can in a large measure be overcome.

The proposition before us now is that we should assist the London Chamber of Commerce to form an electrical trade section. This is not a new idea, for it has often been spoken of, and was suggested by me to the Chamber more than a year ago. There were, however, at that time difficulties in the way of the scheme being carried out; but now that the Electric Lighting Act has been amended we may expect the industry to enter upon a new phase, and united action will become more important than ever.

We are indebted to the editors of *Electrical Plant* for reviving the suggestion that we should avail ourselves of the organisation of the London Chamber of Commerce, and in view of the public meeting which the Chamber will shortly convene in regard to the matter, the present is an opportune time to point out the advantages which the proposed arrangement offers.

The Chamber consists of firms and individuals, and anyone feeling an interest in the transactions of the Chamber can become a member upon payment of an entrance fee of two guineas and an annual subscription of one guinea. Its work is divided among different trade sections, which are again divided into sub-sections according to the needs of the respective industries.

The sections are composed of representative men selected from the members, and one member of each section is elected to the general council. In this way each trade is brought into communication through its representative with all the other trades represented by the Chamber, whilst the various trade sections are not precluded from taking independent action in regard to their own esoteric affairs. The status possessed by the Chamber would at once secure to the electrical industry an influence in Parliamentary and official matters which would be practically unattainable by a separate association formed under existing conditions. The Chamber has been established many years, has done much good for other industries, and its organisation and its mode of procedure are well defined and intelligible, and the secretary of the Chamber has had a large experience in the best methods of promoting and defending trade interests. We should therefore have the enormous advantage of being relieved from the unprofitable work of defining the precise functions of an organisation and of settling its constitution and rules. All that is necessary is that those who are concerned with the commercial interests of the business should allow themselves to be nominated as members of the Chamber, and then elect a representative section or committee. We should not have to concern ourselves with questions of ways and means, for all necessary office accommodation, staff, and a good central place of meeting would be provided for us by the Chamber.

The monthly *Journal* and the annual volume of *Proceedings* published by the Chamber afford means of intercommunication, and of permanently recording the work of the Chamber in regard to our affairs. The facilities of the Chamber for obtaining reports on the state of the industry in other countries and for collecting statistical information are such as no separate association that we could form at present could hope to secure. The following extract from a recent annual report of the council will indicate the special advantages offered to individual members:—

"Although the more immediate object of the Chamber is to serve the interests of members in their collective sense, it is also sought, within the limits of impartiality and fairness, to assist individual subscribers, not only by the communication of information as to treaties, tariffs, prices, foreign legal procedure, foreign exhibitions, the registration of trade marks, and the issue of certificates as to local trade customs, but also by the influence of the Chamber being employed to obtain the support of H.M. Government to members' interests in foreign countries. . . . It is not too much to say that there is very little information in or out of the office which cannot now be obtained and transmitted with the least possible delay."

It may perhaps be urged as an objection to the proposal that those members of the industry who are resident in the provinces would feel themselves excluded, but the membership of the Chamber is not limited to persons residing in the metropolis, and the inconvenience to which country members are put by the meetings being held in London must necessarily apply to every organisation having its head-quarters in London. On the other hand, those members of the industry who join the provincial Chambers of Commerce are brought into communication with the members of the London Chamber by means of the Associated Chambers of Commerce, a central body which represents now some 70 Chambers of Commerce in all parts of the United Kingdom.—Yours, &c.,

112, Belvedere-road, Lambeth, S.E., E. GARCKE.
July 16, 1888.

THE CONDITIONS OF REGULATION IN DYNAMOS FOR CONSTANT POTENTIAL.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The very low induction which, as I read them, Mr. Esson's figures disclosed, led me naturally enough to imagine that his extra exciting power was to be debited chiefly to self-induction. The explanation which is now given by him entirely alters the affair, and is, I think, fully sufficient for the maintenance of his point.

Mr. Esson has, since my previous letter, pointed out to me a reaction from the armature upon the field which I must own to have overlooked, and which is, I believe, very often confused with the self-inductive effects. It may be sometimes concluded that, since the cross-magnetisation of the armature on the whole exerts no influence upon the field, no diminution in the E.M.F. occurs on account of a current flowing through it. But it appears that the lead of the brushes involved by the magnetic distortion due to this current causes a direct weakening influence on the field. This Mr. Esson points out is due to the windings enclosed by the angle of lead on both sides of the theoretical neutral line acting differentially to the field winding, and the effect is therefore almost directly proportional to this angle.

I think that a further weakening effect as a function of the angle of lead may be due to the virtual reduction of section in the air gap by the crowding of the magnetic lines towards the end of the pole-piece remote from the armature pole of like sign.

The remedy for all these evils seems to be a high magnetic density in the armature, and a large number of commutator segments; both the self-induction and the magnetic distortion will then be minimised.—Yours, &c., GUY C. FRICKER.

WHO IS CHEESBOROUGH?

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Commenting on Mr. Justice Kay's judgment in the great incandescent lamp case, *The Times* of this morning says: "The material used by Cheesborough was not invented by *him*; others before him had selected it as suitable for electric lamps. He took a material produced in one quarter, a discovery made in another, and the inchoate results of a great deal of general groping after the attainment of uniformity of composition and section in carbon filaments. He put these things together, and produced a very interesting combination, but it is extremely hard to say exactly how much of the result belongs to him. *He* gets all the reward, however; and not only so, but is enabled to take toll from all the incandescent lamps that are manufactured, as well as to throw considerable obstacles in the way of further improvement."

It would enlighten some of your readers, and be very instructive, if you could give them some idea of the personal appearance and biographical antecedents of this bad man. Is he as great a rogue as he appears, or does he look a greater rogue than he is?—Yours, &c., IGNORAMUS.

July 17, 1888.

[In our issue of 4th May, p. 728, we explained that Cheesborough is a patent agent, in whose name the inventions of Messrs. Sawyer and Man (who are aliens) received protection.—ED. *E.*]

"LIGHTNING IN AN ELECTRIC INSTALLATION."

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Your impression of July 13th contains two distinct and most important reports upon lightning which I think should be read and studied most carefully by all interested in the electric lighting industry. Read as you may and in what language you choose, the reports upon thunderstorms vastly differ; but more so the opinions of the various observers. The natural conclusion we may be allowed to draw from it is that we know precious little about it; and the sooner we set about the thorough study of the phenomena the better.

As far back as 1859, being engaged in making a primitive Morse relief writer, I had my left hand upon the insulated knob of the key, and in my right hand I held a wooden handled screwdriver, with which I was trying to adjust a screw. Suddenly my body was thrown backwards, head raised, arms rigid. I felt the last moment was coming, but my eyes were fixed upon a ball of bluish phosphorescent mass 1½in. in diameter, rolling slowly on the side of two trunk wires in the corner of the room. I was bound to follow the awful spectacle, as if in a mesmeric state. I found myself at last relieved; the ball had vanished, and only left us traces of its former presence, a distinct sulphurous strong original smell. (I say original because Prof. Krausse and myself shortly after the occurrence tried to find out the similarity of the smell; but we could not succeed, although we burnt all sorts of metals in all known gases.) I thought so much of this experience, and so greatly was I interested in the phenomena, that I read up all I could get hold of on the subject of atmospheric electricity, but I could get no information as to the previous observance of the phenomenon which I have described. The only substantial proof of its reality, and one which could speak for itself, was my *screwdriver*, the blade of which was converted into a saw of minute but very regular teeth. A second experience dates from 1882, when in the North of England I had charge of an installation of six 1,000 candle-power arc lamps supplied from an alternating-current machine, all in series, over a range of nearly 1½ miles. The cable was carried upon ordinary wooden posts. It had rained very hard, and there were signs of a heavy thunderstorm. I thought here is a chance at least to observe the phenomena of atmospheric discharge *versus* an unprotected circuit of a high potential. I was not at all disappointed in my expectation. The lightning struck the furthest lamp from the dynamo, melted the clamp pieces of a cut-out, and the melted brass ran in such a way as to make immediate contact, which caused the lamps to relight, and the whole circuit was in proper working order. My engineer, however, observed the effect at the moment upon the dynamo. Ever since, without wishing to be an alarmist, I declare it to be our duty to study the element of lightning, and whenever possible to adopt means to protect *all* electric-lighting installations.—Yours, &c., ERNST FAHRIG.

24, Listria Park, Stamford Hill, London,
July 12th, 1888.

COMPANIES' MEETINGS & REPORTS.

Eastern Telegraph Company (Limited).

The 32nd half-yearly ordinary general meeting of this Company was held yesterday (Thursday) at Winchester House, Old Broad-street, under the presidency of Sir John Pender, K.C.M.G.

The SECRETARY (Mr. George Draper) read the notice convening the meeting, and the report of the Directors was taken as read.

The CHAIRMAN stated that the revenue for the past six months had been £359,706, or £27,844 in excess of the revenue for the corresponding period of the previous year. These figures included the dividend of £31,200 on their investment in the Eastern and South African Telegraph Company, which was £7,800 more. Nearly all the shares in that company belonged to the Eastern Company. Owing to an interruption of the cable they had received £1,300 less from the Black Sea Telegraph Company, but they were not without hope that the final dividend for the year from that Company would make up in some measure the lower interim distribution. Their investment in the Ordinary Shares of the Direct Spanish Telegraph Company, in which they had a controlling influence, had given them a return of £676 against *nil*. That company had now turned the corner, and would, they expected, in future give a good dividend to its shareholders. The total working expenses had been £87,134, or £4,099 more than in the corresponding period of the previous year. The expenses attending repairs and renewals of cables had been £38,412, or a decrease of £5,491, although they had charged under this head the whole cost of duplicating the Zante-Patras section, about sixty miles. Therefore, after charging all expenses, including income-tax, interest on the Debentures, Debenture Stock, and Preference Shares, they were able to pay a dividend and bonus at the rate of 6 per cent. per annum, and to carry to the general reserve fund £75,000, carrying forward a small balance of £884 to next account. They had charged the whole cost of triplicating the Porthcurno-Malta cable and extension to Zante to the reserve fund, which was thus left at £342,338, which, with the special reserves stated in the balance-sheet, made the total amount of the reserves £362,606. They had also charged the amount expended on the new ss. "Amber" to the maintenance of ships fund. The issue of the Four per Cent. Mortgage Debenture Stock to pay off the Five per Cent. Debentures was now complete, and the premium on the issue of the same, £2,366, had been credited to the reserve fund. That was a remarkable instance of the strong position which their stock held on the London market. The total capital of the Company amounted to £5,900,000, and the capital expenditure to £5,965,000. They proposed to make arrangements to dispose of the £62,000 of Six per cent. Debentures of the Direct Spanish Company, and when that was complete the capital and the capital expenditure would practically balance. They would then be able to increase the investments on account of their reserve funds. The extraordinary withdrawals, partly from the reserves and partly from the revenue, had enabled them to keep down their capital, and he hoped in future to maintain their very steady and respectable dividends, and at the same time increase their reserve fund, which was a most important fund for such a company as this. With a strong reserve fund at their back their shares would be regarded on the market not for speculative purposes but as an investment. He might summarise the accounts as follows:—The gross revenue was £27,844 more; the balance brought forward from last half-year was £16,305 more than in the corresponding period of 1887; and the total expenses, including ships and income-tax, were £3,341 less, so that they were able to place £27,000 more to the reserve fund and to pay £19,000 more (or ½ per cent. more) bonus than in the corresponding period of last year. He thought he had now placed a most satisfactory statement before the shareholders. Just before coming to the meeting he had referred to the remarks which he made at the last half-yearly meeting—a meeting which he would always remember on account of the very kind observations which were made by shareholders at the honour which had been conferred on him, an honour which he had accepted as being connected with an institution by which they had all so long stood. In reading over his remarks on that occasion he found that he had made certain prophecies. He then said that in all probability, with the progress they were making, they would be able to pay the shareholders the 1 per cent. bonus which had been temporarily taken away from them on account of the reductions in the rates which were forced on them at the Berlin Telegraph Conference. They had recouped their position, and they were that day enabled to pay their regular 5 per cent. dividend, with a bonus of 1 per cent., thus placing the shareholders in the position they held before the reduction of the rates. He thought that they must regard that as a very satisfactory statement. During the past year they had added immense strength to their system by the laying of a third line from Porthcurno to Lisbon, Gibraltar, Malta, and Zante, giving them another important cable, and thus making them independent of the French line through France. They were, however, so anxious to have their work done in a thoroughly efficient and prompt manner that they were still desirous of having the line through

Digitized by Google

France. They had been in negotiation for a considerable time with the French Government, but there had been difficulties in the way. With the merging of the Submarine system into the Government system, the French people would be free to deal with them respecting the line through France. He believed that there was a spirit abroad among the nations that the great system in which the shareholders were interested was now more or less international, and that while contributing nothing to it they derived the same benefit from it as we enjoyed in England. He believed that the feeling was gaining ground, and he was so far hopeful in the future that they would find less difficulty than heretofore in negotiating with foreign Governments. They had an instance of that at this moment in Portugal, where there was a disposition to meet them fairly. They would endeavour to encourage that feeling, as far as possible, for the more feeders the Company had the better for the shareholders. They were doing a most satisfactory business at the Cape, but feeling that that system was not as perfect or as secure as they would like it to be, they were about completing arrangements whereby they would obtain an alternative route from the Cape, joining their system at St. Vincent, and utilising the line lately laid along the West Coast of Africa. That would give them greater security, and meet a requirement of the Government—in short they would thus have such an independent position that their strength would be naturally increased. They had been strengthening the position of the Company in every way. He concluded by moving the following resolution :—

"*That the printed report and accounts of the Directors to the 31st of March, 1888, submitted to this meeting be, and the same are hereby received and adopted. That a dividend on the Preference Shares of the Company to the 30th of June, 1888, at the rate of 6 per cent. per annum, be paid, less income-tax, and that, in accordance with the Directors' recommendation, a dividend be and is now declared of 2s. 6d. per share, with a bonus of 2s. per share, both free of income-tax, on the Ordinary Shares of the Company, making, with previous payments by way of dividend on account, a total payment of 6 per cent. on those shares for the year ended 31st March, 1888.*"

The VICE-CHAIRMAN (the Marquis of Tweeddale) seconded the motion.

Captain GOODSALL put a few questions, and

The CHAIRMAN having replied, the motion was put and carried unanimously.

A vote of thanks to the Chairman, Directors and staff for their able and successful conduct of the Company's business during the past year was then proposed, seconded, and carried unanimously.

The CHAIRMAN acknowledged the vote, and the proceedings then terminated.

[We shall publish a full report of this meeting in our next issue.]

West African Telegraph Company (Limited).

The third ordinary general meeting of this Company took place at the offices, 98, Cannon-street, on the 13th inst., under the presidency of Major-General Sir Fred. J. Goldsmid, C.B., K.C.S.I.

The SECRETARY (Mr. R. N. Moir) read the notice convening the meeting, and the report of the Directors was taken as read.

The CHAIRMAN : I think only very few words will be necessary for me to add to the report, as it is itself a statement of facts and figures. I should like to call your attention to the meeting of last year and to what was said at that meeting. I think you will find that any promises that were made or any expectations held out have been as far as possible fulfilled. There are one or two things over which we have had really no control. For instance, the traffic has not increased to that extent that we should have been glad to see, but in other respects I think you will find that the working has been satisfactory, and the whole line is at the present moment in good condition and good order. You will remember that at the last meeting it was stated that six stations had been opened in addition to the previous line from Senegal to Sierra Leone. Those six stations were from Grand Bassam to Loanda, through Accra, Kotonou, Sao Thomé, Gaboon, and Principé. It was shown last year that the amount of revenue was somewhat small, but no material or defined explanation was required, because we could state to you that the receipts were only for three months, while the expenditure was for very nearly the whole year. This year has been different. This year has been a year of working, and revenue and expenditure may be much more fairly contrasted. Again last year we had to explain that in starting a line there were a great many expenses which naturally occur in the first year of working an undertaking of this kind ; and this year, though it is not actually a year of starting, still there are many expenses that I think will not naturally follow in after years, because this is really only the second year of working. With reference to our subsidies I may say a few words. You will remember that at the last meeting it was represented that there were some difficulties in the way of realising the subsidies and guarantees until the accounts were placed on a clear footing. Since that period it will be satisfactory to you to know—and it is important you should know this—that the French subsidy has been paid to the end of 1887, and that the Portuguese guarantee has been paid up to the end of September last year. There is now, therefore, every reason to suppose that those payments will be regular and our accounts be put into a more systematic groove. We have no reason to anticipate any difficulties in the receipt of those payments. In that respect we are in a more flourishing condition than we were in last year. I should now like to say a word or two as to the smallness of the traffic receipts. Statistics for the complete line are available from September, 1886, but it would hardly be fair to compare the first three months' working of the complete line with the corresponding period in 1887. Taking, however, the first five months of the present year and comparing the number of words with that of the corresponding period in 1887, after making due allowance for the loss resulting from the interruption on the Sao Thomé-Loanda section, we may fairly consider that the volume of traffic has increased at least 15 per cent. For the present we must rely on our guarantee and subsidy hoping for better results in the future, when the system is connected with the Cape. It is, however, satisfactory to note when considering the returns of traffic that, whether we take the first three months of 1888 as compared with the corresponding period of 1887, or the last six months for which we have received accounts as compared with the six months immediately preceding, there is in each case a slight increase apparent, showing that the tendency is in the right direction. We have endeavoured to economise the working expenses by giving over two of our stations to the African Direct Telegraph Company. The cost which this arrangement will entail will be far more than compensated by the saving in establishment expenses. I do not think I need enter into any further details now, but probably what will be more interesting to you, as to myself and the Directors generally, is something in connection with our prospects. I have received a letter from Mr. Gray, who is unfortunately not able to be present to-day, but he wishes me to read it as coming from the India Rubber Company, with which we are so intimately connected. The following is the letter, which is dated the 10th inst.:—"I understand that your ordinary general meeting takes place on Friday, and that you may wish, in dealing with the prospects of the West African Telegraph Company, to make some reference to the probability of extending the cable from Loanda to the Cape of Good Hope. Anticipating this wish, I may say that this Company is earnestly working towards the completion of this extension, and we have every hope that by the end of this year the connection will be made. When the new lines are completed, the West African Company's property will be enhanced in value on account of the new traffic which will be thrown over this Company's lines. As the negotiations are at present under treaty I am unable to give you further details, but should we be successful in carrying the matter through you cannot fail to see how the increasing of the feeder to your system without any expenditure on your part must be to the advantage of your Company." I do not think you require any statement from me to show that the prolongation of the line to the Cape of Good Hope will be of enormous importance in a pecuniary point of view, and that it ought considerably to increase the receipts of the Company. I will not detain you any further, but will propose

"*That the report and accounts be received and adopted, and that the proposed dividend of 3s. per share be accordingly paid.*"

Sir HENRY C. MANCE, C.I.E., M.Inst.C.E., seconded the motion.

The CHAIRMAN expressed his readiness to answer any question, but no shareholder rising to address the meeting he put the motion and declared it carried. Continuing, he proposed a resolution for the confirmation of the appointment of Mr. Edward March Webb as a director of the Company.

Mr. JOHN MILES seconded the motion, and it was carried unanimously.

Sir HENRY MANCE then proposed the re-election of the retiring Director, Mr. Robt. Kaye Gray. He expressed his regret at the absence of Mr. Gray, who, however, he stated, was in Lisbon on business connected with the Company. They had derived the greatest possible benefit from Mr. Gray's intimate knowledge of the affairs of the Company from the time of its inception.

Mr. MILES seconded the resolution, which was carried unanimously.

On the motion of Mr. LLOYD, seconded by Mr. WELLS, Messrs. Kemp, Ford and Co., chartered accountants, were re-elected auditors of the Company.

An extraordinary general meeting was then held.

The CHAIRMAN stated that the object of the meeting was, as they would have observed from the notice, to correct an error in the Articles of Association. The alteration was quite inevitable. The resolution was as follows :—

"That the Articles of Association be amended in manner following, that is to say :—

"(*a*) Article 31 (as altered by the special resolution passed on the 20th of July, 1887, and confirmed on the 8th of August, 1887) shall be rescinded, and the following Article shall be substituted for it, namely :—

"'81. The number and qualification of the Directors may from time to time be altered and fixed by a resolution of a general meeting in accordance with the Company's regulations, but, until otherwise fixed, the minimum number of the Directors shall not be less than three, and the maximum number shall not be more than nine, and no one but a member of the Company who shall hold in his sole name registered shares or stock of the Company of the nominal value of not less than five hundred pounds shall be eligible as a Director.'

"(*b*) Article 84 shall as from the date of the said special resolution, passed on the 20th of July, 1887, and confirmed on the 8th of August, 1887, be deemed to have been and shall henceforth be rescinded, and the following Article shall as from the date of the said special resolution be deemed to have been and shall henceforth be substituted for it, namely :—

"'84. The continuing Directors at any time may act notwithstanding any vacancy in their body, provided always that in case the Directors shall at any time be reduced in number to less than the minimum number for the time being fixed by the Company's regulations or a resolution of a general meeting, it shall be lawful for them to act as Directors for the purpose of filling up vacancies in their body, but not for any other purpose,'"

Mr. MILES seconded the resolution, which was carried unanimously.

On the motion of Mr. WELLS, seconded by Mr. LLOYD, a vote of thanks to the Chairman and Directors was passed.

The CHAIRMAN, in reply, said he believed that the Directors had all done their duty conscientiously, and so long as they might be on the Direction he felt sure they would continue to do so. They would be only too delighted when they could pay a larger dividend.

The proceedings then terminated.

Digitized by Google

The Telegraph Construction and Maintenance Company (Limited).

The half-yearly general meeting of this Company was held on Tuesday, at the offices, 38, Old Broad-street, E.C., Sir Daniel Gooch, Bart., M.P., in the chair.

Mr. W. SHUTER (the Manager) having read the notice convening the meeting,

The CHAIRMAN said: Gentlemen, the object of this meeting, I think, is rather for you to make inquiries than for me to make any speech, because there is not anything to speak about. During the last six months our ships have been chiefly employed in repairing cables, and they have done that so far successfully. They have been engaged in picking up a cable at a depth of 2,200 fathoms, and they are still employed in that work. We are, I hope, in a position to do a good deal more of that work in the course of the current half-year. You will have seen, I have no doubt, because it is advertised, that we are paying an interim dividend at the rate of 10 per cent. for the past half-year, and the dividend warrants go out to-morrow.

Mr. SHUTER: They go out to-night.

The CHAIRMAN: So that they will be in your hands to-morrow. I am afraid I have nothing to tell you more. Our manufactories have been tolerably busy on other work besides cables, and we are satisfied so far with the work of the past half year; but I shall be happy to answer any question any shareholder wishes to put.

After a pause,

The CHAIRMAN continued: If there is no question I am afraid that this meeting is at an end. These meetings are not very useful ones; they bring you here for very little purpose. However, it was your desire to have them, and we are only too glad of course to meet you. There is no resolution to submit.

Mr. LOUIS: Can you give us any information about the Bermuda cable? Has it been advertised for?

The CHAIRMAN: No. There is nothing doing in reference to the Bermuda cable. It is a very necessary cable, and it ought to be laid. However, there is nothing doing about it at the present moment.

A vote of thanks to the Chairman and Directors then terminated the proceedings.

The India Rubber, Gutta Percha, and Telegraph Works Company (Limited).

A half-yearly general meeting of this Company was held at the Cannon-street Hotel, on Thursday last, for the purpose of obtaining the sanction of the shareholders to the payment of an interim dividend of 5 per cent., or 10s. per share, free of income-tax. Mr. S. W. Silver presided.

The SECRETARY (Mr. William J. Tyler) having read the notice calling the meeting,

The CHAIRMAN said: Gentlemen, the business to-day is of a very formal nature. Before I move the adoption of the motion that calls us together I think I should say that the year's operations thus far have been of a satisfactory character; so much so that we look forward to meet you at the close of the year, when our books are made up, and to present you with accounts which will fully justify the motion referred to, namely,

"*That an interim dividend of 5 per cent., or 10s. a share, free of income-tax, be declared, payable on and after the 20th inst.,*"

which I now move.

Mr. NEIL BANNATYNE: I beg to second the motion that the Chairman has just moved.

Mr. WEBBER said that seeing that the dividend last year only amounted to £13,000 he would like to ask whether the telegraph works were now in full swing, or whether they were only partially employed. In the last balance-sheet it was stated that they had 120 miles of cable, and he wished to know whether that was disposed of. Looking at the balance-sheet of the Telegraph Construction and Maintenance Company of last year he saw that they found employment for their ships when they were not required for cable laying; did this Company adopt the same principle. By the last balance-sheet of the Company he had referred to he saw they made a balance of £88,738 net profit, while this Company only made the paltry dividend of £13,000. He was quite at a loss to know how it was that one factory could not keep pace with another. Seeing that they had a balance at their bank of £30,000, he wanted to know why it was that their coal merchants were told that they must take a four months' bill for the coal they supplied. Many people who might otherwise supply the coal were turned away entirely on account of that, which he considered an outrageous way of doing business. He thought also that the coal should be put up to tender. Other people did so, and he thought it would be advantageous for the Company to do likewise.

General TREVOR asked whether the accounts were sufficiently made up to enable the Directors to state that the 5 per cent. now proposed to be paid had been actually earned out of the profits of the half-year's working.

The CHAIRMAN: I think, as we meet here for a special purpose, we scarcely expected to have these questions put to us; but at the same time we are quite prepared to give the very best reply we can. As regards the India Rubber Works, the telegraph portion is only partially employed. The 120 miles of cable that you spoke of is earning a good return. As to our ships, we lose no opportunity of seeking employment for them; in fact, one has been engaged in the service of the Italian Government. The question relating to coal I shall leave the managing-director to reply to. As to the accounts about which General Trevor asked a question, I should say that our books are made up only once a year, and I can add nothing to what I have already said on that point.

General TREVOR: You cannot say, then, that the 5 per cent. has been earned out of profits?

The CHAIRMAN: Yes, our impression is that we have earned it.

Mr. GRAY (the Managing-Director): In reference to the remarks that Mr. Webber has made as to the way in which we are supplied with coal, I have no doubt that Mr. Webber feels a little aggrieved that he cannot sell coal to us, he being a coal merchant. He has offered us coal from time to time for the last two or three years, but either the price or the quality has not been so good as we could get elsewhere: and because he is a shareholder he has put forward claims now and again to get a preference which I do not feel inclined to give to anybody, I do not care who he may be. I do not think there is any trading concern in London that buys on better terms than we do. We do not pay a higher cost for them; in that he is entirely mistaken. And as for the quality of the coal, I have a regular test taken every week, and it is reported to me, showing the value of the coal that we are getting; in fact tests are going on all the time, and I have returns every week showing how much water can be evaporated per ton of coal. It is done in the most careful manner, and I do not know that there is any place in London where the coals can be tested with greater care and accuracy. I feel perfectly certain that they are bought well. We are not bound to anybody for them. The man that we get the coals from I have never seen, and nothing is done in the way of making contracts but under my instructions. We buy where we can buy cheapest in the interests of our shareholders.

Mr. WEBBER said that he had offered the coals at less cost.

Mr. GRAY: It is not true.

Mr. WEBBER said it was true. He was perfectly independent of their coal contract, and could do without it.

The CHAIRMAN then put the motion to the meeting, and it was carried unanimously.

Mr. HANSON then proposed a vote of thanks to the Chairman and Directors for the care and attention that they had given to the affairs of the Company. He knew a little how business was conducted in the City of London, and he thought he was right in stating that a more efficient Board for conducting such affairs as theirs did not exist. He also expressed the hope shadowed forth by the Chairman, that in February, 1889, the accounts would not only be so satisfactory as to afford them a 10s. dividend, but he trusted that the Directors would be able to see their way to resume the old dividend, and pay them a pound a share.

The motion was seconded by Mr. TREBLE, and carried unanimously.

The CHAIRMAN briefly acknowledged it, and the proceedings terminated.

The Maxim-Weston Electric Company (Limited).

An extraordinary general meeting of this Company was held at Cannon-street Hotel yesterday (Thursday), in compliance with a requisition from shareholders, to appoint additional Directors.

Mr. Hugh Watt, M.P., occupied the chair.

The SECRETARY (Mr. John Wright) having read the notice convening the meeting, and, at the wish of a shareholder, the requisition of the shareholders,

Mr. LOUIS HIRSCH formally proposed that five gentlemen be elected as additional Directors.

Mr. ROSE seconded the motion.

The motion was carried unanimously.

Mr. HILDYARD then submitted that the following gentlemen should be added to the Board in compliance with the motion:—Messrs J. M. Klench, John Marks, G. H. Hildyard, W. D. Harvest, and J. G. Couchman.

A SHAREHOLDER asked how many shares each of these gentlemen represented.

Mr. JOHN NEWTON said that Mr. Klench held from 250 to 500, and Mr. Marks something like 700 to 1,000. Mr. Hildyard, he was sure, was one of the largest shareholders, very few gentlemen surpassing him in point of their interest in the concern. Mr. Harvest also stood in the position of a large shareholder, as also did Mr. Couchman. In short, there could be no possible objection to any of those gentlemen on the ground of their stake in the Company.

The CHAIRMAN wished to explain that he was never opposed to an addition to the Board. He thought that it should consist of more members than as at present constituted. It might be invidious for him to say what the numbers should be—five or seven. He would leave that entirely to the meeting. Personally, since their last meeting, he had not sold a single share, holding, as he did, still 8,000 or 9 000 of them. With regard to the gentlemen named, they were all qualified to act as Directors. If he might be allowed to make one observation, he would say that it was usually a very difficult thing, according to his experience, to get the largest shareholders in a company to act as directors, or, indeed, to take any active part in relation to its affairs. He thought that if they could get business men of high character and reputation to accept a seat at the board of any company they ought to consider themselves extremely fortunate. He would venture to say that the position of the Company now was a very different one from what it was in 1883, when a committee was formed, consisting of Mr. Swaby and himself, to take up the electric lighting industry at a time when it was undoubtedly discredited throughout the country. Millions of money had been lost in it, and he thought he might say that for the years 1885-6, when they paid 7½ per cent. and 5 per cent. dividend, they did a feat unexampled in the history of electric lighting in this country. So far as he was concerned, he would welcome any addition to the Board calculated to improve and extend the connection of the Company, thus enabling it to have a more prosperous career in the future than it had in the past. Up to October or November, 1887, there was every prospect of being able to pay 5 per cent., but three or four very large con-

Digitized by Google

tracts fell through, which did not allow them to do so. The accounts for the year were presented on the same basis as in previous years, with this exception, that the amounts credited to patents were less than in previous years. He wanted to mention one fact with regard to the position of the Company. Of course internal dissension meant destruction, and when those gentlemen came to him a week ago or so and suggested a compromise, so that the committee and the Board should meet there on that occasion, if he might say so, presenting a united front to the shareholders, he for one offered no objection. If those five gentlemen were determined to join the Board and throw in their lot with the present Directors, he thought the shareholders would act in a very suicidal manner if they did not accept of their services, not only cheerfully, but with acclamation. The secretary had prepared a statement of contracts in negotiation between March and July this year, and he found they amounted to £120,000. Six corporations were now in treaty with the Company with a view to very considerable contracts, while contracts were being negotiated with several of the largest railway companies in the country and with other companies besides. They were also in negotiation with two or three departments of the Government for several contracts, as well as with some private firms who seemed to be under the impression that they could carry out such contracts on equal if not on superior terms to those of any other electric lighting company doing business at the present time. Their prospects, therefore, were, he thought, all that could be desired. He did not intend to say anything whatever as to the gentlemen who were proposed to join the Board. He would only say to the shareholders—theirs be the duty of appointing them, as it ought to be; and as to the gentlemen appointed, theirs be the responsibility. He sincerely hoped the Company would succeed, and he believed it would. He had a strong belief in the Maxim patents. The Weston machine was rather an expensive one, but they were now in a position to manufacture it. They manufactured all their arc lamps, and the only thing that they did not manufacture was their incandescent lamp. Referring to the recent decision in the case of the Edison and Swan Company *v.* Holland, he was happy to say that the Maxim-Weston Company had not been threatened with any action in this country, while he was equally happy to state that in the event of such a contingency arising, by their agreement with the American Company they were entitled to a very considerable sum from that Company to defend their patent rights. He hoped that no litigation would ever ensue. It now remained with the shareholders to say whether the gentlemen nominated for seats at the Board—all of whom had conformed with the Articles of Association, inasmuch as they had been nominated seven days prior to the present meeting, and no other nominations having been received—should be elected. To have only two Directors was absurd, and that was practically what they now had, because the last accounts he had of Mr. Brown's condition were very unsatisfactory. Personally he thought there could be no objection to seven Directors, but he thought it was extremely desirable that, whatever action the meeting took, it should be done harmoniously, so that as a company they might present a united front to their opponents, for at no time in the history of electric lighting had opposition been so fierce as it was at the present time. But notwithstanding this fact, as he had said, he found railway companies, private firms, and others going to the company and saying that they would prefer its system to any other. During the present week they had the offer of a contract in London which they refused at a price something like 15 per cent. in excess of the tender of another company, which accepted it, the terms of payment being twelve months. While on that question he ought to say this—and he had not concealed it from anybody—that it was extremely desirable that the Company should have more capital, because if they had not, they would be heavily handicapped in their operations. The expenses connected with installations, such as for the engines, boilers, cable, and so on, were very heavy, and if they were required to give twelve months credit to compete with their rivals it necessitated a large capital. One company, he believed, had been taking contracts on the three years' system—that was to say, by dividing the payments over three years. He thought he would take this opportunity of explaining so far the position of the Company to the meeting.

Mr. HILDYARD then formally proposed, and Mr. WHITE seconded, the election as Directors of the Company of the gentlemen already named.

The CHAIRMAN put the motion, which he declared carried.

Mr. SWABY then, amid a scene of great confusion, demanded whether any of the books and other valuable documents of the Company were missing, and loudly protested that the meeting had been illegally called.

Mr. HIRSCH reminded the Chairman that the business which the shareholders had been summoned to transact having been finished the meeting was at an end, and the question should not be answered.

Mr. KLENCK returned thanks for the newly-elected Directors, assuring the meeting that their earnest desire would be to promote the interests of the Company, and if they found anything "fishy" in connection with its management they would take the first opportunity of laying it before the shareholders.

Mr. SWABY still persisted in putting his question, but

The CHAIRMAN, having first proposed a vote of thanks to the committee, which was duly seconded and passed, vacated the chair.

Mr. JOHN NEWTON said that the committee had fought a good battle for the Company. They had used every effort to put an end to litigation, having made, as they had heard from the Chairman, a compromise. That compromise was only made because they represented a vast sum of money in the Company. If they had only consulted their feelings there would have been no compromise, but they should have fought to the bitter end. They wanted peace. In conclusion, he asked them to vote a sum of money that would cover the expenses of the committee in connection with their investigations.

Mr. GEORGE RUSSELL: How is it to be done? The business is concluded.

Mr. SWABY: I should subscribe my share if we got a fair and not a false balance-sheet. (Uproar.)

A SHAREHOLDER: How much do you want?

Mr. KLENCK said that two committees had been working since March, but he thought 100 guineas would cover everything.

At this point the proceedings became exceedingly noisy and irregular, there being no chairman of the meeting, and

On the motion of Mr. KLENCK, seconded by a SHAREHOLDER, Mr. Louis Swaby, one of the Directors of the Company, was invited to preside.

Mr. RUSSELL said that Mr. Watt had informed them that two members of the committee formed a quorum. If that was in accordance with the Articles of Association of course it could not be altered, but he wished to know whether the gentlemen newly elected would take care that more than two were present at every meeting.

Mr. NEWTON said the matter could be simply settled by the shareholders emphasising the principle of paying fees to those gentlemen only who attended the meetings.

The CHAIRMAN, in answer to a shareholder, said that he believed Mr. Watt had sent in his resignation.

Mr. NEWTON said that Mr. Watt would retire at the end of October, so he had told the committee. But let there be no mistake, it was not to their interest to quarrel with Mr. Watt. They might desire to do so, and no doubt many would like to have something more than a mere quarrel with that gentleman. But he (the speaker) did not, because he was a shareholder of the Maxim-Weston Company, and wished to improve the value of his investment. No one had a stronger feeling against Mr. Watt than he had, but he was not going to jeopardise his interests in the Company by a futile indulgence in personalities.

The CHAIRMAN then proceeded to give an account of his own stewardship in connection with the Company and the manner in which he had been vilified in public in connection with the Company's management, with the object of vindicating himself before the shareholders, but——

Mr. NEWTON interposed and said that the question was not before the meeting and could not be gone into. Besides, Mr. Swaby had been justified in a court of law, and what more could he want? They all knew that he had been justified, and had no need to repeat that justification now.

The CHAIRMAN: Very well, I will drop the subject.

Mr. MARKS objected to the proposed grant of 100 guineas to the committee, for the reason that they were now holding an informal meeting, the proceedings at which could not be held binding on the Directors.

Mr. KLENCK did not believe in doing anything for nothing. They had expended certain sums of money, and they ought to be reimbursed.

Mr. NEWTON thought that 50 guineas should cover their expenses.

Mr. RUSSELL said it could not be passed as a resolution, but might be made in the form of a recommendation to the Directors.

A long and noisy discussion ensued at this point as to the amount to be granted to the committee; and finally, on the motion of Mr. J. H. JONES, seconded by Mr. LEE, it was resolved

"*That the Directors be recommended to reimburse the committee of shareholders for their outlay in the interests of the shareholders a sum not exceeding 100 guineas.*"

Mr. HENDERSON raised an animated debate by wishing to move that Mr. Watt be forthwith suspended from his seat at the Board. The discussion was continued for some time with equal heat by both Mr. Watt's partisans and opponents, the meeting ultimately terminating in "the most admired disorder," without coming to any resolution on the subject.

Western Counties and South Wales Telephone Company.

An adjourned meeting of the shareholders of this Company was held on Thursday, July 12, at the Royal Hotel, College Green, Bristol, for the purpose of sanctioning the raising of additional capital to enable the Company to carry out contemplated extensions. Mr. Charles Nash presided.

Mr. H. F. LEWIS (secretary and general manager) having read the notice convening the meeting,

The CHAIRMAN said it had been thought desirable to defer the arrangement for issuing a further amount of share capital, so that the first resolution attached to the report was withdrawn, and he now moved the second resolution, which was as follows:—

"That the Articles of Association be altered in manner following, that is to say:—

"(*a*) The following article shall be substituted for Article 71, namely, 'They may borrow any sum or sums of money on such security and terms as to interest or otherwise, as they may deem fit, and may secure the same by mortgage or other debentures, or by bond or other securities, or by any mortgage or charge of, or upon, the whole or any part of any property, funds, assets, or effects of the Company, or its uncalled capital; but so that not more than £20,000 be owing at any one time without the consent of a general meeting, and provided that no part of the said sum of £20,000 shall be borrowed without the consent of the United Telephone Company (Limited), and no borrowed money shall, without the like consent, carry interest at a higher rate then 6 per cent. per annum.'

"(*b*) In Article 91, the word 'and' coming after the word 'agencies' shall be omitted, and the words 'trunk lines and new business' shall be inserted after the word 'branches.' The clause, as amended, shall apply as from the formation of the Company."

The sum mentioned (the Chairman continued) might be sufficient to carry them through the present year, and they hoped that money would be obtained at a lower rate of interest than if share capital had been offered—probably not exceeding 5 per cent. He would just repeat what he thought he said at the last meeting, viz., that it was necessary they should have

Digitized by Google

further capital in hand to enable them promptly to cover some further portion of the large district which formed the territory of the Company. It would be their duty very carefully to select from the long list of places mentioned in the report those that were likely to give them a speedy return, and to arrange for opening exchanges in them, and also for connecting them, where desirable, by trunk lines. The only other point, he thought, was that it would not be necessary to borrow the whole of this money at once. That would be done at intervals as required. The last clause of the resolution was only inserted for the purpose of removing ambiguity and making the meaning of the clause plain. There had been a doubt as to whether it included trunk lines or not, and there would be no doubt about it any longer, as these words made the matter perfectly plain. He would only add that the general progress of the company continued to be very satisfactory, and that from week to week they were getting considerable accessions of business. Since they last met there were two places where arrangements were now in progress for speedily opening exchanges—he referred to Cheltenham and Swindon. Perhaps they might not be very valuable in themselves, but Cheltenham, when connected with Gloucester and the Stroud district, and Swindon, if connected with Bath and Bristol, would, he believed, bring a very considerable increase to their business.

Mr. MARK WHITWILL seconded the motion, which was carried unanimously.

The CHAIRMAN said he should like to supply an omission he made at the annual meeting in June by expressing what he was sure was the feeling of the Directors, their high appreciation of the great energy and ability of Mr. Lewis, the general manager. During some very heavy work that had been going on lately, Mr. Lewis had been very ably supported by the members of the staff. They often had to work long hours. That they had done willingly, and he thought it was only due to them that it should be mentioned.

Mr. HENRY FEDDEN said he had seen a great deal of Mr. Lewis's work and would like to confirm what the Chairman had said in regard to it. He never knew a man who was more earnest in his work than Mr. Lewis, who had shown a thorough determination to make the company a success.

Commander D. M. FORSYTH, R.N., also testified to the great help which Mr. Lewis had rendered, both in the formation of the company and in its subsequent development.

Mr. LEWIS briefly returned thanks, and the meeting terminated.

Petroleum Engine Company.

The statutory meeting of the Petroleum Engine Company (Limited) was held on Wednesday last at the Cannon-street Hotel, E.C., Mr. Henry Pawson presiding.

The SECRETARY having read the notice convening the meeting,

The CHAIRMAN said: This meeting is called simply in compliance with the statute which regulates companies' affairs. The business may be purely formal; but there is this fact, which it may not be out of place to mention—in fact, I have great pleasure in naming it—the Royal Agricultural Society have within the last few days awarded its silver medal to this Company for its important invention. There were only two silver medals awarded. The Society can award for new mechanical inventions within the year as many as 10 silver medals. On this occasion there were no fewer than 69 applications for medals, but only two were granted; and this Company, for its petroleum engine, occupies the first place. Now, this, as you will not be surprised to learn, has caused a great number of applications to be made to our licensees, Messrs. Priestman Bros., for information regarding this important invention, for it has not become known to everyone yet. It will be one of the exhibits at the Highland Agricultural Society at Glasgow in the course of next week, and I have no doubt it will attract as much attention there. Orders are coming in now, and our licensees, Messrs. Priestman Brothers, are erecting extensive workshops for the purpose of producing engines rapidly; and although I am not in a position to tell you what amount of business has been done at the present time, yet I can entertain no doubt that we are on the eve of a great business, and in due time I hope we shall be in the happy position of being able to declare a dividend.

Mr. DUNLOP asked had the whole of the Company's capital of £100,000 been issued, and were there any debentures or charges on the property outstanding?

The CHAIRMAN said there were no charges of any kind against the company. All the shares were allotted, with the exception of a very small reserve.

Mr. WALLACE said in purchasing his shares he was influenced a great deal by the well-known reputation of Messrs. Priestman Brothers. He concluded his remarks by putting a series of questions to the Chairman, a copy of which he handed in.

The CHAIRMAN, in reply, said the Company absolutely controlled all the patents of the engines for Great Britain, India and the British Colonies, including those taken out by Messrs. Priestman and Hume. The Company's guarantee that Messrs. Priestman would adequately introduce and push forward the sale of engines was that they had expended many thousands of pounds of their own capital in the concern, and the only return they could obtain was from the manufacture and sale of the Company's engine, out of which the Company received a royalty. Messrs. Priestman were not interested in any other motive power invention which could come in competition with the petroleum engine. The Directors' remuneration was £100 a year each, and there were four of them. The Directors had decided on measures which would very considerably reduce the yearly expenditure of the Company. Measures were being taken—and the Board expected very important results—to introduce the invention in the Colonies and India and push it to the fullest extent. It was true that the special oil used in lighthouses by the Trinity Corporation had been tested for working the Company's engines and found suitable for that purpose. The result was most satisfactory. The Company did not defray any of the expenses of advertising and otherwise for making the invention known.

In reply to Mr. MICHIN, the CHAIRMAN said the Company had nothing to do with the Company working the petroleum engine in the United States; that Company would not in any way trench on their ground.

The shareholders were then invited to elect an auditor, and, on the motion of Mr. IRVING, seconded by Mr. TIPPING, unanimously appointed Mr. Ernest, who had been carrying out the duties.

Mr. MICHIN moved, and Mr. TIPPING seconded, a vote of thanks to the Chairman, which was carried.

The proceedings then terminated.

Anglo-American Telegraph Company (Limited).

Report of the Directors to the ordinary general half-yearly meeting of the proprietors, to be held at Winchester House, 50, Old Broad-street, London, E.C., on Thursday, the 26th inst., at 12 noon:—

1. The total receipts from 1st January to 30th June, 1888, including the estimated balance of £2,344. 18s. 4d. brought forward from the last account, are estimated at £77,575. 18s. 8d. This amount, however, is subject to revision, dependent upon the result of the law suit still pending between this Company and the Paris and New York Telegraph Company. The traffic receipts show a decrease, as compared with the corresponding period of last year, of £19,635, the reasons for which are explained in paragraphs 6 and 7 of this report.

2. The total expenses of the half-year, including repair of cables, &c., as shown by the revenue account, amount to £42,189. 6s.

3. One quarterly interim dividend of 5s. per cent. on the Ordinary Stock, and of 10s. per cent. on the Preferred Stock, was paid on 1st May, 1888, absorbing £17,500, and a second quarterly dividend of 5s. per cent. on the Ordinary Stock, and 10s. per cent. on the Preferred Stock will be paid on the 1st of August, 1888, absorbing £17,500, leaving a balance of £390. 12s. 8d. to be carried forward to the next account.

4. The Company's repairing ss. "Minia" has been engaged during the past half year in the repair of the St. Pierre-Duxbury cable, broken off Cape Sable, N.S., and of the Northern Placentia cable, near St. Pierre. The Island Cove cable, broken by an iceberg, was repaired by the officers of the station at Heart's Content.

5. The 1873, 1874, and 1880 cables are in good working order, but the interruption to the Brest-St. Pierre cable, announced in the last report, still continues; the ss. "Minia" is now engaged in effecting the repair, and as she has already made satisfactory progress, the Directors have every reason to believe that communication by this cable will be restored before the close of the season. The St. Pierre-Duxbury cable was again broken on the 28th May, at a distance of 299 knots from the latter place. The Company's system of cables and land lines in Newfoundland and Prince Edward Island is working satisfactorily.

6. The traffic passing over the lines of the joint-purse companies during the past half year shows a considerable decrease as compared with the corresponding period in 1887. This decrease is explained principally by the fact that the Commercial Cable Company reduced their tariff from 1s. to 5d. per word on the 15th September last, thereby entering into competition with the associated companies at equal rates.

7. The Directors regret to report that the very encouraging increase of traffic, the principal part of which followed immediately upon the reduction to 6d. per word on the 5th May, 1886, has not been continuous, and has now practically ceased, for although Atlantic cable traffic is much larger than that carried to any other part of the world, it does not develop with sufficient rapidity to admit of the present tariff being made permanent. The result of over two years' experience of the reduction of tariff from 1s. 8d. to 6d. per word has been an augmentation in the volume of traffic of about 140 per cent., and this fact proves beyond question that with the present system of coding messages, and with the large number of competing cables, exceptionally low rates upon such long and costly lines of communication cannot be made to pay. The Directors trust that arrangements will soon be made between all the companies for the establishment of more remunerative rates.

8. The attention of the public has been frequently drawn, through the Press, to the large amount of the Company's capital, and this is alleged to be the sole reason why low rates cannot be made profitable upon the cables of this Company. The Directors, in answer, would point to the fact that the margin between revenue and working expenses produced by the 6d. rate is too insignificant to show sufficient profit upon any amount of capital necessary, even at the prices of materials and labour now current, to relay or renew such a system of cables and land lines as that possessed by the Company, without taking into consideration the absolute necessity of building up a substantial renewal fund, which is now admitted on all hands to be indispensable to the permanent existence of cable companies.

9. The appeal of the Paris and New York Telegraph Company against the judgment of the Tribunal of Commerce, in favour of this Company, came on for hearing on the 10th April. The Court of Appeal decided that before final judgment could be given reference must be made to the Conseil de Prefecture for the interpretation of certain administrative matters in connection with the concession of the Paris and New York Company. The Directors fear that the final decision in the case will not be obtained for some months, as either of the parties to the suit has the option of appealing to the Conseil d'Etat, and which will probably be availed of.

LEGAL INTELLIGENCE.

The United Telephone Company v. Tasker, Son and Co.

In the Court of Appeal on Wednesday last this case came before Lords Justices Cotton, Fry and Lopes as an appeal against a decision of Mr. Justice Kay (which we reported last week), who had ordered the plaintiffs to extend an undertaking previously given, and to supply the defendants with 96 telephones instead of 52, as at first agreed.

LORD JUSTICE COTTON was satisfied that, though the undertaking was given in general terms, it was given upon the understanding of both parties that only 52 telephones which were infringements of the patent were in use by the defendants, to which 52 the undertaking and the injunction would apply. As soon as the blunder was discovered the defendants ought to have consented to a limitation of the undertaking to the 52 telephones, and his lordship thought that Mr. Justice Kay ought to have been satisfied on the evidence before him that the undertaking had been given by the plaintiffs as applying only to the 52 telephones, and he should have limited the undertaking accordingly. That, his lordship thought, was the undertaking which the plaintiffs intended to give. He did not say that the plaintiffs were bound to give any undertaking, but they were willing to do so, and they had a right to have the undertaking limited to that which they intended to give. With regard to costs, the defendants had made a mistake as to the number of infringing instruments which they were using, and as soon as they found it out they ought to have acceded to the plaintiffs' desire that the undertaking should be limited to that which they intended to give, and ought not to have compelled the plaintiffs to apply to Mr. Justice Kay. The costs, therefore, of the application and of the appeal must be the plaintiffs' in that event.

LORD JUSTICE FRY did not doubt that the misstatement of fact was a *bonâ fide* error on the part of the defendants, or that there was no intention to deceive. But when the error was discovered the defendants ought to have assented to confining the undertaking to the 52 instruments which were in the mind of the plaintiffs when they agreed to give the undertaking.

Lord Justice Lopes concurred.

The Court allowed the appeal.

Re Emile H. M. Andreoli.

In the Official Receiver's Department of the Court of Bankruptcy a receiving order in this case was made, on May 29, the debtor residing at Loughborough Park, and accounts have been furnished showing total liabilities £4,919, of which £3,577 are unsecured, with assets *nil*.

The following is taken from the Official Receiver's observations:—The debtor states that he is a journalist and foreign correspondent, which profession he followed for many years previous to 1878, when, having a small capital, he started a weekly newspaper called *The Paris Exhibition of 1878*, afterwards changed to *Industry*, and acted as editor thereof until August, 1882, the undertaking resulting in a loss. From 1882 to 1884 he was engaged in certain negotiations in connection with Italian railways, which also proved unsuccessful. The debtor further states that he has been engaged in electrical experiments, which he has conducted with borrowed moneys, and has taken out two patents, and that in 1886 he started a French paper (*L'Ingénieur Electricien*), which was published in Paris until January, 1887. Since the beginning of the present year he has been engaged in experiments in electric bleaching, from which valuable results are anticipated.

NEW COMPANIES REGISTERED.

BARNOLDSWICK GAS AND LIGHT COMPANY (LIMITED).—This company was registered on the 7th inst., with a capital of £12,000 in £10 shares, to manufacture, sell, and supply gas or any other illuminating power in the parish of Barnoldswick, in the county of York, and generally to carry on the business of gas manufacturers and gasfitters, electrical engineers, and every other business in any way connected with the manufacture and sale of gas and electricity, or other illuminants. The subscribers are :—

	Shares.
H. Slater, Barnoldswick, manufactrrer	120
J. Pickup, Barnoldswick, general dealer	50
J. Broughton, Barnoldswick, mason	40
J. D. Roberts, Barnoldswick, physician	40
S. Slater, Barnoldswick, pork butcher	60
C. Brookes, Barnoldswick, grocer	15
J. Hartley, Barnoldswick, innkeeper	20

The number of directors and the names of the first directors will be determined by the subscribers to the Memorandum of Association. The company in general meeting will determine remuneration.

GREENWOOD AND BATLEY (LIMITED).—This is the conversion to a company of the business of engineers and machine makers, carried on at the Albion Works, and elsewhere in Leeds, by the firm of Greenwood and Batley. It was registered on the 7th inst., with a capital of £400,000 in £10 shares. The subscribers are :—

	Shares.
*Arthur Greenwood, Albion Works, Leeds, engineer	1
*G. Greenwood, 16, Great George-street, engineer	1
Henry Greenwood, Albion Works, Leeds, engineer	1
*J. H. Wurtzburg, Albion Works, Leeds, engineer	1
*Rear-Admiral P. H. Colomb, 97, St. George's-road, S.W.	1
*Major-General E. Micklem, 36, Hans-place, S.W.	1
*Lt.-col. R. Vivian, 5, Hans-place, S.W.	1

The number of directors is not to be less than 5, nor more than 7; qualification, £500 in shares or stock. The first are the subscribers denoted by an asterisk. The remuneration of the Board for the first five years is to be £4,000 per annum for the managing directors, and £1,000 per annum for the chairman and ordinary directors.

H. DALE AND COMPANY (LIMITED).—This is the conversion to a company of the business of electricians and manufacturers of scientific and mechanical inventions, apparatus and materials, carried on by Henry James Dale and E. J. Dale, at 26, Ludgate-hill, E.C. It was registered on the 5th inst., with a capital of £10,000, in £5 shares. The subscribers are :—

	Shares.
*H. J. Dale, 184, Elthorne-road, Hornsey Rise, electrician	1
E. J. Dale, 184, Elthorne-road, Hornsey Rise, electrician	1
*R. C. Beauchamp, Wormsley-road, Hornsey	1
*E. G. Price, 9, Kirby-street, Hatton-garden, electrician	1
C. D. Smith, 35, Clifton-crescent, Asylum-road, Old Kent-road	1
J. Hulme, Glen Eldon-road, Streatham, accountant	1
W. Jackson, 20, Cornwallis-road, Holloway, electrician	1

The number of directors is not to be less than three nor more than ten; qualification, £100 in shares or stock. The first are the subscribers denoted by an asterisk. The company in general meeting will determine remuneration.

SCIENTIFIC APPLIANCE MANUFACTURING COMPANY (LIMITED).—This is the conversion to a company of the business of electricians and manufacturers of scientific and mechanical inventions, apparatus and material, carried on by Henry James Dale and Edward Jonathan Dale, at 9, Kirby-street, Hatton-garden. It was registered on the 5th inst., with a capital of £10,000, in £5 shares. The signatories and directors are the same as in those of H. Dale and Company, Limited (*see* above), and the same regulations as to qualifications and remuneration will apply.

THE EAST STRAND AND DISTRICT ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—Registered by the Law Land Company (Limited), with a capital of £5,000, in shares of £5 each, with power to increase. Object, to apply and obtain, either singly or jointly, licenses, provisional orders, or Acts of Parliament for the supply of electricity; to establish and carry on the business of suppliers of electric energy, of manufacturers of and dealers in electrical apparatus and appliances, of all descriptions, used or intended to be used in any way in, or which are applicable to, the generation, distribution, storage, measurement, conversion or utilisation of electricity, and the business of an electric light and power company in all its branches, and of engineers and contractors, and such other business as the directors of the company for the time being may consider desirable for the interest of the company. The first subscribers are :—

	Shares.
J. Dunn, F.R.I.B.A., 1, John-street, S.W.	1
G. E. Lloyd, 4, King's Bench-walk, E.C.	1
A. W. Lightbody, 222, Strand, W.C.	1
S. H. Burbury, 1, New-square, Lincoln's Inn, W.C.	1
E. Wilson, 5, Adams-court, New Broad-street, E.C.	1
A. M. Lloyd, Norfolk House, Victoria Embankment, W.C.	1
J. G. Lorrain, Norfolk House, Victoria Embankment, W.C.	1

The company is registered without Articles of Association, and, consequently, the regulations of Table A of the Companies Act of 1862 apply.

CITY NOTES, &c.

ANGLO-AMERICAN TELEGRAPH COMPANY.—The Board of Directors of this company have declared an interim dividend for the quarter ended 30th June, 1888, of 5s. per cent. on the Ordinary stock, and 10s. per cent. on the Preferred stock, less income-tax, payable on the 1st August, to the stockholders registered on the books of the company on the 10th July, 1888.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended July 13th, 1888, amounted to £4,582.

ELECTRICAL PURIFICATION COMPANY (LIMITED).—The acquisition and working of patents granted to Mr. W. Webster relating to the electrical treatment of sewage will be undertaken by this company.

GLOBE TELEGRAPH TRUST COMPANY.—The Directors of this company have declared a final dividend of 3s. per share, less income-tax, on the Preference shares, and of 3s. per share on the Ordinary shares, free of income-tax, making with the previous payments, a dividend for the year of 6 per cent. on the Preference shares, and 3½ per cent. on the Ordinary shares.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended July 13th, 1888, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company, were £3,789.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half month ended July 15 were £2,525, as compared with £2,398 in the corresponding period of last year.

PERSONAL.—We are informed by Mr. S. Sudworth that he has left the firm of Sudworth and Co. (Limited), electricians and manufacturers, of South Hackney, and has established himself as an electrical engineer and contractor for electric light installation work. Mr. Sudworth omits to mention his present address.

Offices—**WINCHESTER HOUSE, OLD BROAD STREET, LONDON, E.C.**

The principal objects of the Corporation are:—

1. Performing the duties of Trustee, Executor and Administrator.
2. The Insurance of Bonds, Shares and all other Securities lodged with the Corporation against risks of all kinds.
3. The Issue of Warrants and Certificates against Securities deposited, and making and procuring advances on such Warrants.

The Office of Trustee or Executor is to private persons usually a thankless post, involving much anxiety, time and money, and frequently leads to serious actual loss; whilst death, illness and change of residence necessitate frequent fresh appointments, and consequent expense to the parties interested. The Corporation undertakes all the duties of Executor, Trustee or Administrator for reasonable remuneration proportioned to the work and responsibility in each case.

The Corporation insures existing Trustees and Executors against all risks attending those positions, where the business is conducted by the Solicitors to their Trusts under the supervision of the Corporation, it not being the desire of the Corporation to interfere in any way with the duties of the family solicitor.

The Corporation acts as Trustees for the Debenture Holders in Public Companies.

For terms, &c., application should be made to the General Manager at the Company's Office.

GEORGE PEARSON, *General Manager and Secretary.*

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL SCIENCE, INDUSTRY AND ENGINEERING.

No. 532.—Vol. XXI. FRIDAY, JULY 27, 1888. Price 4d.

NOTES.

We would direct especial attention to the meeting which is to be held at Botolph House (12, Eastcheap) at 3 p.m. this (Friday) afternoon, which will be called upon to decide the question of the formation of an Electrical Section of the London Chamber of Commerce. The promises of support which the movement has already received are both numerous and influential, and we anticipate that a representative gathering will attend the meeting this day. In case any of our readers have not yet received a copy of the circular which has been issued by the Chamber of Commerce, we reprint the text further on.

With reference to the statements made by the Lord Mayor, in his speech at the Mansion House Banquet to the English Committee of the Paris Exhibition, on Saturday evening last, we cannot but express surprise at the inadequate manner in which English electrical industries threaten to be represented. The English exhibits as a whole will fully represent the manufactures of this country, but those representing the industries in which we are especially interested will, as we have said, be very meagre and incomplete. Many of our largest firms are holding aloof, although we understand that appeals, both personal and otherwise, have been made to them by various representatives of the Paris Exhibition Executive Committee, and by the Society of Telegraph-Engineers and Electricians. It is presumed that the feeling generally is that exhibitions do not pay We doubt this very much. They may not pay directly—that is, few or no orders may be traced to the exhibitions themselves—and we may be told that French tariffs practically exclude many articles of English manufacture; but in cases of this kind sometimes the benefits accrue long after the effort has been made, and an exhibition in Paris does not mean an exhibition only to Frenchmen but to the world. Those who have articles which are worthy of introduction to South Americans, Chinese and Japanese may all find a convenient centre for the display of their wares at the forthcoming Paris Exhibition. We trust that even yet it is not too late to find some of our leading firms avail themselves of the saving clause by which the Lord Mayor held that, although the present space was fully appropriated, yet some extra room might be found for exhibits of a specially interesting character that might come in at the eleventh hour.

The formation of the Metropolitan Electric Supply Company, with a capital of £500,000, is probably the most important step which has yet been taken with a view to the supply of electric light in the metropolitan district upon a wholesale scale. The particulars given yesterday morning by one of our financial contemporaries, though a little premature, are in the main correct. Our contemporary is of course in error in saying that the new company has obtained a provisional order "covering the district from Piccadilly in the west to Lincoln's Inn-fields in the east," the fact being that it is one of the objects of the new company to take over several minor concerns which are already in the field, and which have applied for provisional orders covering a portion of the above area. Amongst those is the Whitehall Court Company, whose central station is already well advanced towards completion. In addition, the new company has secured a valuable site in the neighbourhood of Lincoln's Inn-fields, and also an extensive wharf at the south end of Waterloo Bridge, where, we believe, the principal works will be established. The list of names connected with this enterprise furnishes the fullest guarantee for its success both from a financial and an engineering point of view. Sir William Thomson and Dr. John Hopkinson will be the consulting engineers, while Mr. J. E. H. Gordon and Mr. J. B. Verity will join the Board.

In connection with the process of sugar refining by electricity, about which various rumours have been afloat, a correspondent of the *Scotsman* tells a rather singular story. According to this authority, the cost of producing by this method a ton of refined sugar of 99·9 per cent. purity does not exceed 3s. 9d., which it appears is equivalent to a saving per ton of no less than £4. The process of boiling the sugar and the use of charcoal are entirely done away with, and all that has to be done is to feed the raw juice into one hopper and to watch the refined sugar issuing continuously from another. All this certainly sounds extremely promising, and electrical engineers may, perhaps, anticipate a very large demand for dynamos from the sugar refiners. We much regret, however, to have to state that there is just one point on which we do not feel entirely satisfied. We naturally want to know how it is done. It appears that the Company which controls the process was formed as long ago as 1884, with a nominal capital of one million dollars, of which 600 shares (amounting to 600,000 dollars) were assigned to the late Prof. Henry Friend, the inventor of the process. But, strange to say, it was part of the agreement with Prof. Friend that the method of working was never to be disclosed to any

Digitized by Google

human being, not even to the chairman of the company. Notwithstanding this drawback, however, so much confidence was felt in the good faith of the Professor that extensive premises were erected in Brooklyn at an outlay of over £5,000, and machinery was ordered intended to turn out 500 tons of sugar per day. The manufacture and erection of the machines occupied more than two years, since to avoid the least inkling of the purpose they were to fulfil the orders were given in small sections at various works; and the machines were afterwards put together by the Professor himself, with the assistance of his wife and two near relatives. In the innermost recesses of this mysterious factory there was a "secret room," access to which was most jealously guarded by day and night. Over the portal an inscription warned the intruder that one step within the forbidden chamber would be attended with instant death. When all was ready the Professor invited the president and directors of the company to witness a small private "demonstration." They were conducted to a room which contained nothing but a table, upon which stood the electrical apparatus covered with a white cloth. They themselves supplied the sugar to be refined, and, although they were not allowed to lift the cloth, they were satisfied that there was really no deception, and that the room contained nothing besides—excepting, of course, the Professor himself. They then solemnly mounted guard for one hour and three-quarters outside the door, and at the end of that time, on being permitted to re-enter the room, they found that the whole of the raw sugar had been converted into snow-white glistening lumps. So far, so good; but, unhappily, on the 10th of March last, and before the process had been set to work on a commercial scale, Prof. FRIEND died.

IT appears, however, that prior to his death the Professor had committed the details of the process to writing, and that this precious document is now in the possession of the President of the Electrical Sugar Refining Company. We sincerely trust that the process will prove as great a success on a practical scale as it appeared to do while in the hands of the inventor; if not, we fear that some people will be grievously disappointed, as we learn that even in Liverpool and in Birmingham the shares have recently been dealt in at 400 per cent. premium. The company are very likely carrying out a sound commercial policy in keeping the process secret rather than in applying for patent protection, but in view of the history of the enterprise as now disclosed it is difficult to understand how full confidence can be felt until business has actually been done. It is said, however, that a factory will shortly be started in this country.

OTHER things being equal, we think that it is a matter for congratulation when an electric lighting scheme is undertaken by a local company, in which the consumers or the ratepayers are themselves the largest shareholders. The movement is one to which we have every reason to wish the fullest possible success, and which we hope to see extend throughout the country. We are, therefore, all the more anxious that no false step should be taken, particularly in a financial direction, by any of the limited number of such companies already in existence. For this reason we are unable to feel much satisfaction at what has just taken place in Bath. Mr. MASSINGHAM has undertaken to supply 70 lamps, with a 6-ampere current, at £19. 17s. 6d. per annum, or 17 per cent. less than the price asked by the lowest of the three firms who would have used the same system. We shall be relieved to learn that Mr. MASSINGHAM is in possession of such substantial advantages over his competitors as will justify his company in taking the contract at so low a figure.

"INSTALLATION RULES" are found to be a prolific source of discord in the electrical camp almost all the world over—although, perhaps, we should make an honourable exception of the New England States, where the question has been dealt with by a joint committee of electrical engineers and the fire-insurance companies. The latest quarrel of this description has arisen in connection with the Technical Commission appointed by the Paris Municipality to frame regulations for installing electric light in theatres, and has resulted in the resignation of M. MASCART. The point in dispute is whether the use of non-inflammable scenery and decorations should be made compulsory in connection with the electric light. M. MASCART has recently carried out some experiments (see *The Electrician*, June 22, p. 201) on the liability of textile fabrics to be set alight by contact with the globes of incandescent lamps, and it was proved that under certain conditions this is possible. But at the same time he arrived at the conclusion that the contingency is too remote to demand the employment of special precautions. The Commission, however, decided by a small majority to enforce the use of non-inflammable decorations in all theatres, whereupon M. MASCART has sent in his resignation. For our own part, we should be sorry to oppose even superfluous precautions for the prevention of fire in theatres, especially in those which are lit by electricity, seeing how much the credit of electric lighting is at stake in such installations.

A LETTER from the Board of Trade, and the discussion which followed it at a special meeting of the Dublin Corporation last Tuesday will be found in another column, and will well repay perusal. The local gas company has done its utmost to prevent the intrusion of the electric light into Dublin, and has even moved the Board of Trade for compensation on account of the gas company's plant thrown out of use by the substitution of electricity. This the Board has of course refused, and on other points has shown itself friendly to the proposals of the Corporation. It is satisfactory to notice also that Mr. MAYNE, on behalf of the defunct electric lighting company, was able to give a good account of its performances while it lived, and a satisfactory reason for its being wound up. For every sixpence-worth of plant that the company owned they had, Mr. MAYNE assured the meeting, done a full amount of business, and it was only because extension of plant became necessary just at the moment when the industry was being discredited by financial speculators that the shareholders insisted on winding up the concern rather than supply more capital. The Corporation have now determined to take the matter into their own hands.

We reproduce this week, from a Transatlantic source, a traveller's account of what he saw of the English telegraph system and its operators in the desert wastes and cities of Persia. Mr. Thomas Stevens's descriptions will be none the less interesting to many of our far-distant readers for the characteristic Americanisms which embellish his Paper; and as a testimony of what our cousins think of us it will be hardly less welcome to English readers at home.

It is gratifying to learn, from an answer in Parliament the other evening, that the English Government have not yet given any thought to executions by electricity in this country, notwithstanding the alleged bungling of the present Lord High Executioner. Painful incidents on these occasions are not peculiar to modern executions, and are, we suspect, only rendered peculiarly painful by the presence of the modern reporters. Recent experiments, we are glad to notice, have satisfied even the New York public that the ghastly details which these gentlemen delight to furnish would probably not be wanting in the case of an execution by means of electricity.

Our Paris correspondent gives an account of an important scheme for an underground electric railway which it is proposed to carry through the centre of Paris, and which we should much like to see realised. As a mere feat of engineering such a railway would be more interesting, quite as ornamental, and possibly even more useful than the Tower of Babel which the Parisians are so enamoured of at present. The scheme in question is a somewhat ambitious one, but, so far as the technical details are concerned, we have no doubt that it can be carried to a completely successful issue.

We wish we could speak with equal confidence of the probable success of the scheme at present under consideration for working the Metropolitan Railway by electric traction. We have already, on more than one occasion, expressed our disapproval of the attempt to apply secondary batteries to this purpose. But the success or failure of the scheme is fraught with so much import to the immediate future of electric locomotion that we feel constrained to recur to the subject. The fact is, the more we think about it the less we like it. To discuss the question in full detail at the present moment would perhaps be unfair, but when the proper time arrives we shall not shrink from doing so. Meanwhile, there is just one point upon which we may offer an observation. The companies who have had the greatest experience in the manufacture of accumulators in this country are practically unanimous as to the total weight required per horse-power for cells giving two hours' discharge. This they put at 7cwt. For engines of 600 horse-power, as proposed, this means a dead weight of 210 tons for the accumulators alone! But we understand that the weight of the accumulators is estimated by the promoter of the scheme in question at only 50 tons. It would be satisfactory to know how this discrepancy arises. What is thought about the scheme in America may be seen in the letter of our New York correspondent which we publish to-day.

The negotiations between the Atlantic cable companies with reference to the adoption of a shilling tariff are still going on, but are now limited to the question of agreement with the French Pouyer-Quertier Company, and as that company is in litigation with the Anglo-American Company, the adjustment of their differences is not quite settled. The agent of the French Company has been over here for some days, and has now returned to Paris for further instructions.

Lloyd's Signal Stations Bill.—This Bill was read a third time in the House of Lords on Friday last and passed.

Electric Traction in India.—The *Indian Engineer* says that arrangements are being made to introduce electric-motor cars into Madras.

Leeds.—Messrs. Mather and Platt, of Manchester, have obtained the contract for the lighting by electricity of the new Fine Art Gallery at Leeds.

Dewsbury.—The Dewsbury Town Council has decided to adopt the electric light in all the rooms of the new Town Hall, and Mr. Wilson Hartnell, of Leeds, has been instructed to carry out the work at a cost of about £2,000.

South Hampstead.—We understand that some of the inhabitants of South Hampstead have placed themselves in communication with the Anglo-American Brush Corporation, with a view to the establishment of a central lighting station in that district, and that a practical scheme is likely to be arrived at.

The Proposed Cable to Bermuda.—In the House of Commons on Friday last, Mr. Raikes, replying to Sir E. Watkin, said he was afraid he could give no further answer than that the question of connecting Bermuda with Halifax, Nova Scotia, by telegraphic cable, was still under the consideration of the Treasury.

Export of English Electric Lighting Plant to America.—We have learnt with much pleasure that Messrs. Hammond and Co. have recently received a large order to supply the requisite plant, on the Lowrie-Hall system, for a central electric lighting station in America. This is, we believe, the first order of the kind which has reached this country.

Our "Annual Dinner."—The annual dinner of *The Electrician* staff took place on Monday last at the "George and Dragon," Ightham, near Sevenoaks, under the presidency of Sir James Anderson. The company were favoured with fair weather; an excellent dinner was provided for the forty guests by Mr. Mist, the worthy host, and a most enjoyable day was spent.

Personal.—Referring to an intimation in our last issue, received from Messrs. Woodhouse and Rawson, Mr. A. Reckenzaun writes us as follows:—"With reference to your mention in last week's issue of my appointment to Messrs. Woodhouse and Rawson, I beg to inform you that the same was premature, and was occasioned by negotiations which have since proved unsuccessful."

The Society of Arts' Tests for Prime Motors.—The tests for prime motors initiated by the Society of Arts will take place in September, on the ground belonging to the Imperial Institute at South Kensington, which has been kindly lent for the purpose by the committee of the institute. The preliminary tests will commence on the 12th September, by which date all engines must be fixed and ready for work.

Magneto Bells for Domestic Use.—We are informed that the Equitable Telephone Association (Limited) have been appointed agents for a new system of magneto-electric bells of

Digitized by Google

great simplicity. It is expected that these bells, which have been designed by Mr. E. Cox Walker and Mr. C. C. Campbell-Swinton, will come into extensive use for domestic and similar purposes. They are to be introduced to public notice very shortly.

St. Saviour's District Board.—At a meeting of this Board held last week, a letter was read from the London Electric Supply Corporation, Limited, suggesting that in the provisional order which they are seeking for the supply of the electric light in this district, a clause should be inserted giving the Corporation power to enter into a contract with this Board for the supply of electricity.—Mr. Haggis did not think that this Board wanted to go into trading.—It was determined to acknowledge the letter.

The Zipernowski-Deri System.—We are informed that Messrs. Ganz and Co., of Budapest, have recently received several large orders for electric lighting plant from Australia to supply central stations at Melbourne, Huntershill (near Melbourne) and Huntershill (near Sydney), the first-mentioned station having a capacity of 2,700 horse-power, to be doubled later on. In addition to this orders have been received for central-station plant from Montevideo and Valencia, and for a transmission of power plant to be set up at Rives, France.

Paddington Vestry.—At the last meeting of the Paddington Vestry the Works Committee brought forward a resolution to the effect that prior to making a formal application to the Board of Trade, for a license to supply electricity throughout the Borough, the clerk be instructed to obtain a report from an electrical engineer, at a cost not exceeding £21, as to the probable outlay to be incurred in producing, storing, and supplying electricity for lighting purposes. It was agreed that the £50 should be expended on the matter, as suggested by the committee.

SS. "City of New York."—The new Inman and International liner "City of New York," the largest passenger steamer afloat, is lit throughout by electricity, the dynamos being supplied by Messrs. King, Browne and Co., of Edinburgh. There are in all about 1,000 incandescent lamps, those for the passengers being of 16 candle-power, while a few of larger type are used for cargo-working purposes. The ship is also supplied with a powerful search light. A large ventilating fan on the promenade deck, running at 1,000 revolutions per minute, is also worked by electricity.

The Telephone at Swindon.—A meeting has been held in Swindon to discuss the feasibility of establishing a telephone exchange in that town. Mr. H. Lewis, the energetic manager of the West of England and South Wales Telephone Company, explained the nature of the service, and said that as soon as twenty subscribers were obtained the company were prepared to run a trunk wire to Bath. Through Bath direct communication would be obtained with the extensive system of trunk wires which now find their centre in Bristol. He hoped also that within eighteen months of the present time the line would be completed from Bristol to London, *via* Swindon.

Clark's Standard Cell.—Mr. Durand Woodman writes from Newark, N.J., as follows:—"Sir: May I be allowed to correct an unwitting error in a communication from Mr. Kennelly in your No. 528 of June 29th. The three Clark cells of which he gives a record were not 'set up at the Edison Lamp Factory' nor 'under Mr. Howell's supervision.' They were prepared and set up in my laboratory under no one's supervision, as I was at that time without an assistant. They were made expressly for Mr. Edison's laboratory on an order coming through Mr. Howell, which accounts for the misunderstanding. As I took the entire risk of their performance, I shall consider space for this correction a favour."

Rotherhithe Vestry.—At a meeting of this Vestry held last week, the clerk read a letter from the secretary to the South Metropolitan Electric Supply Company, and Messrs. Deacon, Gibson, and Medcalf, on behalf of the London Electric Supply Corporation (Limited), stating that in the provisional order which they were seeking for the supply of the electric light in the district a clause would be inserted giving the corporation power to enter into a contract with this Board for the supply of electricity. Mr. Down was supporting the proposal, and referring to the importance of the question, which he thought should be dealt with without delay, when several members suggested that the matter should be referred to committee, which was agreed to.

Electric Traction in Australia.—We learn that Messrs. Booth, Ellson and Co., electric tramway engineers, of 5, Queen-street, Melbourne, Australia, have secured the right of tramways for the city of Sandhurst, for the term of 30 years. A large company has been floated by them to carry out the work, and Mr. Ellson (formerly with the Hammond Company, England) is now on his way to this country to make the necessary arrangements for plant, &c. The same firm has tramway schemes on hand in several other towns in the colonies. When once introduced we expect to see as rapid an extension of electric traction in Australia as has lately taken place in America. We wish Messrs. Booth, Ellson and Co. every success in their undertaking, as they have thus initiated one of the largest electric tramway schemes in the British Empire. We may add that letters for Mr. Ellson should be addressed to the General Post Office, London.

An Exhibition of Workmen's Skill.—An interesting exhibition of the skill of workmen in their own trades will be opened at the Crystal Palace on August 18th, in connection with the National Co-operative Festival. The competition will be amongst working-men members of the Industrial Co-operative Societies throughout the kingdom, and the special facilities offered to them to compete, by their respective societies agreeing to pay carriage on all exhibits, should open the door to a very large and representative display of individual work. The prize list is a good one, and the Council of the Society of Arts—who have promised to appoint the judges—will also award one of their bronze medals in eighteen of the principal classes. In addition, there are many classes for all kinds of amateur work, women's work, and children's work, and for collections of various kinds. The secretary, Mr. W. Broomhall, 1, Norfolk-street, Strand, will supply any further particulars.

Ilfracombe.—A special meeting of the Local Board of Ilfracombe was held on Saturday last to consider the question of lighting the Victoria Promenade. A letter was read from the secretary of the gas company stating that the cost of proposed gas fittings for the shelter would amount from £160 to £180, and the gas about 7½d. per hour, or about £50 per annum. A letter was also read from Mr. Woodley, with whom the Board have been in correspondence relative to the introduction of the electric light, offering to light the promenade for £150 for the first year if the Board would pay £60 if the fittings had to be taken away, or he would light the whole town for £680 per annum. A long conversation followed on the subject, and it was finally resolved that the Board should accept Mr. Woodley's terms to light the promenade for one year. The surveyor was also instructed to ascertain the cost of lighting the Parade with electricity, and on the terms being ascertained to submit them to a meeting of the Board.

Digitized by Google

The Lighting of Drury Lane Theatre.—At the meeting of the company of proprietors of Drury Lane Theatre, held on the 21st inst., in the saloon of the theatre, Mr. Percy Lloyd observed that fire was the great thing that had to be guarded against in theatres. Had the committee, therefore, had before them the question of lighting the theatre by electricity? The electric light had been adopted with great satisfaction and success at several theatres, and in view of the many casualties of late years in such places he thought that the committee ought to give their earnest consideration to the question of lighting Drury Lane Theatre with the electric light.—The chairman, in replying, stated that the subject had been very often discussed by the committee, and also with Mr. Harris, and it was now standing over until certain inquiries had been made and certain facts had been ascertained. Nothing had been done at present, but it was obviously the right thing to do if it could be managed. In further reply, he added that the matter would certainly not be allowed to drop.

A Smash.—The *Journal of Gas Lighting* is responsible for the following story—"The directors of the Smedley Hydropathic Company, at Matlock, are introducing the electric light into the public rooms of their establishment. On the 28th ult. (but some considerable time after it was originally expected the installation would have been completed) the light was turned on for the first time. By way of giving suitable *éclat* to the event, a band of music was engaged for the occasion, and a number of persons were invited to be present. The engine was started in the forenoon, and was worked at a low pressure until about eight o'clock in the evening, when an order was sent to the driver to do his best. He obeyed; and in a few minutes afterwards there was a great smash. The two wheels of the countershaft broke—various fragments flying through the windows into the street, to the alarm of the passers by. The dynamo also broke; and, of course, the light suddenly went out. The despised gas had to be lighted, and is now in use again; and we understand is likely to be for some weeks to come."

Adoption of the Electric Light Scheme at Bath.—At an adjourned meeting of the Bath Town Council, held on Tuesday, the consideration of the proposal to accept a tender from Mr. H. G. Massingham, of Bath, to light 50 of the principal streets of the city with electric light on the Thomson-Houston system, with 70 arc lamps, was continued. The details of all the tenders received were reported in our last issue. A lengthy discussion took place. Mr. T. W. B. Cox, who opposed the proposition, said he believed the inhabitants were against the introduction of the electric light. The only successful installation which had been set before them was that at Taunton, but he was not quite sure but that they might hear of a catastrophe there. Just before the division was taken, Dr. Tuckett, a member of the council and a gas shareholder, asked if he could vote. The Town Clerk said the Council had heard the opinion he had read which stated that no persons interested could vote. Having read the law he left the members to do what they thought proper. Twenty-two voted for the resolution in favour of the introduction of electric light, twelve voted against, whilst eight, all shareholders in the Gas Company, abstained from voting.

Smart Telephone Construction Work in the North.—We mentioned last week an instance of quick work in the erection of a telephone line to Lancaster which was carried out by the Lancashire and Cheshire Telephone Company. The following instance, though of earlier date, is even more remarkable:—At the latter end of last year the Northern District Telephone Company received some important orders, and were under heavy penalties to finish the work by the 1st of November. The whole time occupied was 59 working days from the delivery of the first pole by the railway company. Twenty-six miles of new poles were erected, carrying 92 miles of copper wire; in addition to this 89 miles of wire were run on existing pole routes, this including, of course, the necessary arming of the poles, the number of poles being about 700. Two days before the completion of the lines there were several poles still to erect, and no wire was to be seen for over a distance of three and a-half miles on one portion of the route. The lines were, however, in working order at the stipulated time. The whole of the work was carried out by the district engineers, Messrs. C. M. Bailey, T. C. Bayley, and J. A. Jeckyll, under the supervision of Mr. G. F. L. Preston, the company's engineer.

Postal Telegraph Revenue.—The Select Committee on Revenue Departments' Estimates state in their report that they have taken evidence upon the Customs, Inland Revenue, Post Office and Post Office Packet Service, and Post Office Telegraphs estimates for the current year. With regard to the last-named service the committee report that the estimates of the Post Office telegraphs show continuous growth both of expenditure and of the proportion of expenditure to gross revenue. The latest account for 1886-87 shows a balance of profit of no more than ·63 per cent. upon a capital of £12,091,894. Return 31, session 1888, shows that the total deficiency of income to meet expenditure and interest at 3 per cent. on capital created on account of Post Office telegraphs from the 1st of January, 1872, to the 31st of March, 1887, amounted to no less than £3,024,899. The deficiency has latterly been increasing year by year, and for the last year, of which the accounts are included in this return, was £471,889. The unprofitable character of this Government business has been attributed to the high price originally paid for the purchase of telegraphs by the State, to the enormous increase of services gratuitously performed for the railway companies, to the tariff under which press messages are sent causing a loss amounting to nearly £200,000 a year, to unproductive work done for other departments, and to public pressure to improve the service even at a loss.

The International Congress of Electricians.—By a decree of the 16th July, 1888, the Minister of Commerce and Industry has nominated the organising committee of the International Congress of Electricians, which is to take place in connection with Exhibition in 1889. The committee comprises MM. d'Arsonval, Acting Professor at the Collège de France; Berger, ex-President of the Société Internationale des Electriciens; Boudet de Paris, member of the Committee of the Société Internationale des Electriciens; Carpentier, Vice-President of the Société Internationale des Electriciens; Cornu, Professor at the Ecole Polytechnique; Gariel, Vice-President of the Société Internationale des Electriciens; Hospitalier, Professor at the Ecole Municipale de Physique et de Chimie; Joubert, Secretary of the Société de Physique; Lemonnier, President of the Société Internationale des Electriciens; Mascart, Professor at the Collège de France; Napoli, head of the Experimental Laboratory of the State Railways; De Neville, head of the Central Laboratory of Electricity; Postel-Vinay, President of the Chamber of Electrical Industries; Potier, Professor at the Ecole Polytechnique; Raymond, Director of the Ecole Supérieure des Télégraphes; Renard, Director of the Government Workshops at Meudon; Sartiaux, Chief Electrician to the Chemins de Fer du Nord; Sebert, Vice-President of the Société Internationale des Elec-

Digitized by Google

triciens; Séligmann-Lui, Secretary of the Société Internationale des Electriciens; Vivarez, Secretary of the Chamber of Electrical Industries; together with MM. Bouilhet, Bourdin, Delahaye, Fontaine, Hillainet, Lippmann, Pellat, Picou, Touanne, and Violle.

The Brussels Exhibition.—Some additional details which have come to hand respecting the electric lighting of the Brussels Exhibition may prove of interest. The interior of the Exhibition is lighted by 500 Khotinsky incandescent lamps, of 18 candle-power each, and by 244 arc lamps, ranging in candle-power from 1,500 to 2,500. The arc lighting of the buildings is done by the Société Thomson-Houston, MM. Bouckaert and Schuckert, and the Industrielle and Electrique Companies. In the grounds the lighting is divided between M. Pieper and the Anglo-American Brush Corporation. Pieper's installation has been working some time to a partial extent; but owing to there being a deficiency of boiler power the total number of lamps installed have not been regularly in work. The Anglo-American Brush Corporation have 58 lamps of 2,000 candle-power in operation every evening. These are distributed as follows:—10 in British section, six at the switchback railways, six on the high mast opposite the entrance from the Rue de la Loi, and 18 on independent masts all round the grounds; 18 lamps are set apart for the illumination of the arena, which was originally intended for the performances of the hipprodrome. These, however, came to an abrupt termination, but the lamps are still in use and effect a very useful purpose, as they light up a large space which is the prinicpal thoroughfare from the Exhibition buildings to the grounds, and bring into relief one of the most beautiful architectural features of the Exhibition. Some 600 horse-power is altogether employed in driving the electric light machinery, 350 horse-power being used for the lighting of the interior, and 250 horse-power for the lighting of the gardens.

A Scientific Exhibition in the Temple.—The Treasurer of the Inner Temple, Sir Patrick Colquhoun, Q.C., and the Benchers held a scientific "At Home" in the Inner Temple on Thursday evening, the 19th inst., which was attended by a large number of members and their friends. The extensive suite of rooms had been admirably adapted for the purposes of a singularly interesting scientific and artistic exhibition. In addition to the ordinary electric lighting arrangements, both the exterior of the buildings and some of the rooms were illuminated by electricity. In the corridor were shown telephones by the United Telephone Company connected with the Savoy Theatre, and guests were able to listen to the performance of the "Mikado." In the great hall there was an admirable display of arc lamps by Messrs. R. E. Crompton and Co. Sir William Thomson's compass and binnacle and deep-sea sounding apparatus, models of an electric railway, a torpedo boat and a Nile steamer, electric chronograph, telegraph instruments, writing telegraphs, and submarine cables were also exhibited in this department. A fine series of photographs was also on view. In the Parliament Chamber the Electrical Power Storage Company exhibited a battery of accumulators supplying current for various purposes. In a large marquee outside the working of the Maxim automatic machine gun and the Nordenfelt machine gun, electric torpedoes and other recent innovations in the art of warfare were exhibited. Experiments were shown by the Exchange Telegraph Company with their automatic type-printing telegraph instruments, which were connected with the Houses of Parliament. By permission of the Postmaster-General, the great hall was placed in telegraphic connection with Manchester.

The Volta Prize and the Inventions of M. Gramme.—The French Chamber and Senate will shortly award the Volta prize of 50,000fr. for the best application of the voltaic battery, and it may not be without interest, says *La Revue Internationale de l'Electricité*, to recall here the circumstances which originated the founding of this interesting prize. On the 19th Brumaire, year X., the First Consul was present at a meeting of the Institute, and heard Volta read a Paper on the "Electric Battery." The outcome of this was the founding of a prize, which was open to the *savants* of all countries for the best application of this branch of physical science. Electricity seemed to the First Consul to merit special attention, and he doubtless foresaw that it would become in the future a fruitful source of discovery. On the 26th Prairial of the same year the First Consul published the conditions and fixed the prize at 60,000 francs. The first competition opened on the 10th Messidor. We must then go on to the 23rd February, 1852, before we find any notice of the second competition. From this date the value of the prize was reduced to 50,000 francs, and competitions took place more frequently, the dates being 18th May, 1858; 18th April, 1866; 29th November, 1871. These competitions have always borne excellent fruit, the names of Faraday, Ampère, Ruhmkorff, and Graham-Bell being connected therewith. The last competition was opened on the 11th June, 1882, and closed on the 31st July, 1887. A special commission, sitting at the Ministère de l'Instruction Publique, was entrusted with making the award. The members of the commission decided by a majority of votes to award the Volta prize to M. Gramme, "for the improvements made by him in the construction of dynamo-electric machines." The improvement consists in having made a continuous-current machine, which was the starting point of that marvellous development of electrical industries which we are now witnessing. Yet in 1860 M. Gramme was a working carpenter employed by M. Ruhmkorff to put finishing touches to the woodwork of electro-static machines. He soon became fascinated by the world of magic into which he had been suddenly introduced. He hardly knew how to read or write, but this did not stop him; he wished to know, and did know. His resources were of the most modest character. His library consisted of two books, a French dictionary and a work on physics; his laboratory was equally rudimentary, containing only a sheet of gutta percha, two magnets, and a few pounds of copper. In 1868, eight years later, he made his first continuous-current machine; but the impossibility of sufficiently insulating the adjacent wires did not allow him to take full advantage of his discovery. In 1869 he advanced a step, and made a new machine with a 10 kilogramme magnet and an armature wound with 1 millimetre wire. In 1871 M. Gramme devised for M. M. Christophle a machine running at 300 revolutions a minute, and able to deposit 600 grammes of silver per hour. A little later he built another machine for the factory of M. Whohwill, of Hamburg, which gave a current of 3,000 amperes at eight volts, and was able to deposit 800 kilogrammes of refined copper in 24 hours. In these days batteries are completely discarded for electro-metallurgical purposes, and the industrial applications of electricity have multiplied in every country. A vast array of inventors have followed in M. Gramme's steps. The Commission has awarded the prize, in short, to a hard-working, modest man, who has explored the secrets of nature, and who has known how to apply them in the best and most useful way. Electricity owes much to M. Gramme. Thanks to him, it plays an important part in modern times, and will end, we are convinced, by ousting steam from its present position of supremacy.

UNIPOLAR INDUCTION.—VII.

BY G. W. DE TUNZELMANN, B.SC.

(Concluded from page 301.)

In 1880 E. Riecke published a second Paper on "Unipolar Induction" in *Wiedemann's Annalen*, Vol. XI.

In this Paper he gives a short account of Weber's theory set forth in 1839 in the *Resultate aus den Beobachtungen des Magnetischen Vereins*. Weber's explanation of unipolar induction was founded on the theory of the existence of two magnetic fluids in each of the molecules of a magnet, and he made a distinction between ordinary induction due to the action of both fluids, which he called bi-polar induction, and induction due to the action of one fluid only, which he called unipolar induction. Weber at that time considered that his results could only be explained on the hypothesis of these two fluids, and therefore disproved the existence of Ampère's molecular currents. Later on, however, Weber found that this conclusion was not justified, and in his "Electro-Dynamische Maasbestimmungen" he arrives at the conclusion that the phenomena of unipolar induction may be explained, on the hypothesis of molecular currents, by making the additional assumption that such a connection exists between the moving electrical fluids and the material particles of the magnet, that any forces acting on the fluids are completely or almost completely carried on to the material particles.

In this Paper, Riecke discusses the phonomena on the hypothesis of the existence of molecular currents in the magnet, and comes to the conclusion that it gives a satisfactory explanation of them. He finds that both this and the method adopted in his former Paper give the same values for the E.M.F. produced, but he shows that on the hypothesis of molecular currents the effect of a rotating magnet on the element of a fixed conductor will be the same as that of the fixed magnet on the same element, when the latter is made to rotate with an equal angular velocity in the opposite direction. He considers that in view of the other evidence in favour of the existence of the amperian currents this hypothesis is preferable, and suggests that the name Unipolar Induction should be discarded as misleading, and replaced by some such term as "Electro-Magnetic Rotation Phenomena." The investigation of Ampère's method of the action of an element of current on an element of a conductor moving relatively to it involves a considerable amount of somewhat tedious mathematical calculation, and when translated into the language of Faraday's theory of action in the medium it involves the assumption which has been made in these Papers that the magnetic field of a magnet rotates with it.

In 1883, in *Wiedemann's Annalen*, Vol. XIX., F. Koch published an important and elaborate Paper on what he calls, in accordance with Riecke's suggestion, magneto-electric rotation phenomena. In this Paper the subject is approached from the consideration of the potential, which is the mathematical equivalent of Faraday's methods, and the author arrives at the result that the induced E.M.F. has its seat in the fixed portion of the conductor. He also obtains a numerical expression for the E.M.F., which shows that the E.M.F. depends on—

(1) The dimensions of the rotating magnet.
(2) The distance of the magnet from the axis of rotation.
(3) The position of the terminals of the fixed portion of the circuit.

It is pointed out that (2) and (3) do not agree with the results of some of the measurements made by Plücker (*Poggendorff's Annalen*, 1852, Vol. LXXXVII.), and the author suggests that this may probably be due to the fact that the measurements could not be relied on, owing to the variability in the resistance at the sliding contact. A series of quantitative experiments are described which confirm the theoretical conclusions.

In 1886 Dr. E. Hoppe (*Wiedemann's Annalen*, Vol. XXVIII.) published a criticism of Edlund's theory, and described some experiments which he considered showed it to be untrue. His apparatus is shown in section in Fig. 21; *a a* is a tube of soft iron; *b b* is a brass cylinder to which the iron tube is screwed, and by means of which it can be attached to an apparatus for putting it in rotation; *e* is a brass block, into which are screwed a brass rod, *g*, in a straight line with the axis of rotation; and four brass rods, *d d*, insulated from the iron tube by four gutta-percha rings, *e e*. A brass ring, *f f*, is screwed to the four rods *d d*. The other end of the rod *g* is kept in position by the gutta-percha disc *h*. A brass plate, *i*, could be screwed to the axis and joined to the ring *f f* by means of four brass rods, *k k*. The tube was magnetised by means of a bobbin, *l l*, of insulated wire, which remained fixed when the axis was set in rotation. The direction of the magnetising current was in every case such as to make the lower end of the iron tube a north pole.

Experiments were made, in the first place, to show that no currents were produced by the rotation of the apparatus in the absence of the iron tube, which, indeed, would not be expected on any theory.

The following experiments were then made:—

(1) The apparatus, without the plate *i* and the rods *k k*, was made to rotate first in one direction and then in the other, and the magnitude and direction of the current between sliding contacts at *f* and *g* were observed in each case.

(2) The ring *f f* was placed in metallic connection with the iron tube by means of a copper wire, and the currents were observed as before.

(3) The plate *i* and the rods *k k* were fixed to the apparatus, and sliding contacts made at *f* and *g*, and the currents again observed as before. When the sliding contacts were at *i* and *g* no current was produced.

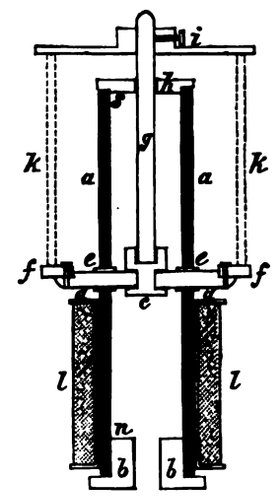

FIG. 21.

a a soft iron tube, *b b* brass cylinder, *c* brass block, *d d* brass wires, *e e* gutta-percha rings, *f f* brass ring, *g* brass rod, *h* gutta-percha disc, *i* brass plate, *k k* brass rods, *l l* bobbin of insulated wire, *n s* north and south poles of magnetised tube.

In each of these experiments the current was from *g* to *f* when the rotation was counter-clockwise, and from *f* to *g* when it was clockwise.

(4) The rods *k k* were then removed, the plate *i* remaining in place, and sliding contacts were made at *f* and at the periphery of the plate *i*. The current was found to flow from *i* to *f* when the rotation was counter-clockwise, and from *f* to *i* when it was clockwise.

Hoppe arrives at the conclusion that—

(*a*) The currents in (1) were in the opposite direction to that required by Edlund's theory.

(*b*) In (4) there should be, according to Edlund's theory, a current from *f* to *i* stronger than the current in (1), while the observed current was weaker and in the opposite direction. As Hoppe points out, this weakening of the current is easily explained if the lines of force are supposed to rotate with the magnet.

(*c*) In (3) the current observed was in the opposite direction to that required by Edlund's theory, and in the case in which no current was observed there should have been one on Edlund's theory.

Digitized by Google

(*d*) The connection of the magnet with the ring *f* in (2) would, according to Edlund's theory, considerably increase the strength of the current, and the induction of the magnet on itself would come into play, whereas in the experiment the connection was found to have no effect on the strength of the current.

Hoppe points out that all his results are capable of being simply explained on the hypothesis of rotating lines of force.

Edlund replied to this in a Paper published in *Wiedemann's Annalen*, Vol. XXIX., and gave explanations of Hoppe's experiments in accordance with his theory. In this Paper Edlund maintains that the assumption of the rotation of the lines of force with the magnet is in contradiction with the observed result that the rotation of a magnet on its axis exerts no effect on a magnetic needle suspended in its field. It is rather difficult to understand how Edlund could have supposed this experiment to have any bearing on the question whether the lines of force rotate or remain stationary, for the direction of the needle depends on the direction of the force acting on it; and this would be the same in either case, for whether the lines rotate or remain at rest, it follows from the symmetry of the field with regard to the axis of rotation that no change will take place either in the magnitude or in the direction of the magnetic force at any part of it on account of the rotation of the magnet. Hoppe's experiments with the electro-magnet are of importance, as from the point of view adopted in these Papers they show that the field of a rotating electro-magnet magnetised by a fixed coil rotates with the magnet, as in the case of a permanent magnet; and though this result was to be expected it is of interest to have it experimentally confirmed.

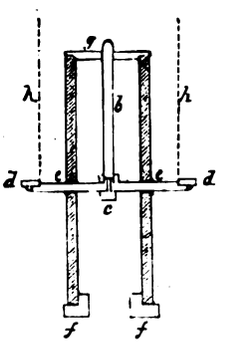

FIG. 22.

b brass rod, *d d* brass ring, *e e* brass rods, *e* brass block, *f f* brass cylinder, *g* gutta-percha disc, *h h* movable copper cylinder.

Hoppe published a further contribution to the subject in the same year (*Wiedemann's Annalen*, Vol. XXIX.), in which, recognising that some difference might possibly be supposed to exist between the action of an electro-magnet and a permanent magnet, he constructed an apparatus (Fig. 22) similar to that employed in his former experiments, but with a tube of steel permanently magnetised in place of the soft iron tube of the former apparatus. *b* is a brass rod, *d d* is a brass ring connected by four brass rods, insulated from the magnet by gutta-percha rings and connected with a brass block *e*; *g* is a gutta-percha disc, and *h h* a movable copper cylinder.

Similar results were obtained as in the former experiments, and it was also shown that the addition of the copper cylinder excited no effect on the current between sliding contacts at the end of the rod *b* and at the periphery of the disc *d*, proving that the mass of the moving conductor had no influence on the induction.

Some experiments were also made by means of an electrometer to see if there were any induced static charges at the end of *b*, or at the periphery of *d*, but the results were entirely negative.

In an appendix to this Paper Hoppe discussed Edlund's reply, and asserted that the latter had modified his former theory to explain his (Hoppe's) experimental results.

Edlund denied this in a Paper published in 1887 (*Wiedemann's Annalen*, Vol. XXX.), and maintained that Hoppe's failure to detect any electrostatic charge arose from his electrometer not being sufficiently sensitive.

In March of the same year Edlund read a memoir before the Swedish Academy of Sciences, which was translated in the *Philosophical Magazine*, 5th Series, Vol. XXIV., 1887.

In this Paper he discusses at considerable length the results obtained by different observers. He attempts to prove mathematically that the induction produced by the rotation of a magnet in an external conductor at rest and at some distance from it is inappreciably small in comparison with the induction produced when the conductor rotates about the magnet with the same angular velocity. This is in direct conflict with the experimental results of Faraday and many other observers, according to which the induction has identically the same value in the two cases.

Edlund's mathematical reasoning is perfectly correct, but it only takes account of the translatory motions of the outer portions of the magnet as they describe circles round the axis, and it is easy to see without mathematical aid that this effect will be exceedingly small. Edlund objects to the theory adopted in these Papers that it is in opposition to the requirements of the mechanical theory of heat—in other words, that it is not in agreement with the conservation of energy.

His contention is based on the explanation of the admitted experimental fact that when a magnet, *n s*, is surrounded by a metallic jacket, shown diagrammatically by *a b* in Fig. 23, in contact at its upper and lower edges with the ends of a wire, *a c b*, and the magnet and jacket are made to rotate in the same direction with the same angular velocity, a current

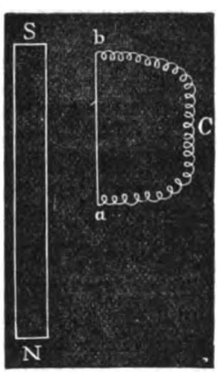

FIG. 23.

n s magnet, *a b* section of jacket, *a c b* conducting wire.

will flow through the wire. The induction is then assumed to take place in the fixed wire, and to be due to the rotation of the magnet. To this Edlund objects that the magnet may be put in rotation in either direction without encountering any resistance other than that due to friction or torsion according to the manner in which it is suspended, and, therefore moves without doing work, and thus cannot generate a current.

The obvious answer to this is that when the magnet is rotated, and the jacket and wire remain at rest, no current is generated, as he admits, and, therefore, no work is required to be done by the magnet. If, on the other hand, the magnet is rigidly attached to the jacket, it cannot be rotated without doing work, because it will generate a current in the wire *a c b*, and this will set up currents in the moving portion of the apparatus tending to oppose its motion.

J. Puluj has recently made some very pretty experiments illustrating unipolar induction, which were described in a Paper read before the Vienna Academy of Sciences in April last.

A hollow copper sphere is suspended by a fibre from a point in a vertical line with the axis of an electro-magnet, and is set spinning. If the sphere is then slightly displaced to either side of the axis of the magnet it is found to describe a circle round the pole in the same direction as its own spinning motion. The effect is easily explained by considering the relation of the currents induced in the sphere to the lines of force proceeding from the magnet.

LETTERS FOR LEARNERS AND UN-PROFESSIONAL READERS.

BY H. D. WILKINSON.

CHAPTER IX.—*Magnetic Fields.*

(Continued from page 307.)

120. *The Magnetic Field of a Magnet in Terms of its Moment.*—Let us suppose a unit north pole at the point n (Fig. 82) on a line bisecting a bar magnet, N S, whose length is l centimetres and strength of each pole m C.-G.-S. units. The unit pole will be acted upon by two forces, one of attraction and one of repulsion, in the direction of a line drawn from S to n and N to n respectively. The magnitude of each of these forces will be $\frac{m}{r^2}$ (para. 108), r being the distance between the unit pole and either pole of the magnet. Now, the resultant of these two forces will be the actual force on the pole, and will be numerically equal to the intensity of field (f) at the point n. On completing the parallelogram, and drawing the resultant f we find by the simple proposition of similar triangles that

$$f : \frac{m}{r^2} :: l : r;$$

whence

$$f = \frac{m\,l}{r^3};$$

and since $m\,l$ is the moment (M) of the magnet (para. 118),

$$f = \frac{\mathrm{M}}{r^3} \text{ in C.-G.-S. units.}$$

Example.—(1) What is the intensity of the magnetic field of a bar-magnet at a point 20 centimetres distant from either pole, the moment of the magnet being 800 dyne-centimetres?

Answer.—Intensity $= \frac{800}{20^3} = \frac{1}{10}$ C.-G.-S. unit.

(2) What is the intensity of the magnetic field due to a bar magnet at a point 30 centimetres away from the centre of the magnet in a direction perpendicular to its length, the strength of each pole of the magnet being 900 C.-G.-S. units and its length 20 centimetres?

Here the direct distance (r) from either pole to the point in the field is not given, and must be calculated from the data

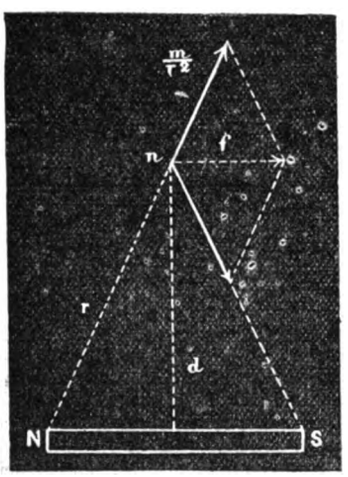

FIG. 82.

given. It will be seen (Fig. 82) that the distance r forms the hypothenuse of a right-angled triangle, of which the other two sides d and $\frac{1}{2}\,l$ are known, viz., 30 and 10. The length r is therefore the square root of the sum of the squares of the other sides (Euclid I., 47)—that is,

$$r = \sqrt{30^2 + 10^2} = \sqrt{1000} = 31{\cdot}62 \text{ centimetres,}$$

and the moment of the magnet $= m\,l = 900 \times 20 = 18{,}000$ dyne-centimetres. Therefore the intensity of the field at the required point is

$$\frac{\mathrm{M}}{r^3} = \frac{18000}{(31{\cdot}62)^3} = \frac{18000}{31620} = {\cdot}569 \text{ C.-G.-S. units.}$$

If the point at which the field is calculated is at a perpendicular distance from the magnet equal to many times its length, we may take the hypothenuse (r) or pole distance from the point as being equal to the actual perpendicular distance, and obtain a very near approximation. This could not be done in the last example without introducing an error of 17 per cent., the ratio of the perpendicular distance to the length of magnet being only as 3 : 2.

Let us now measure the field at a point situated on the continuation of the axis of the magnet, d centimetres from its centre, r centimetres from the nearer pole, and R centimetres from the further pole, supposing that a unit north pole is placed at n at the point required (Fig. 83). It is evident that

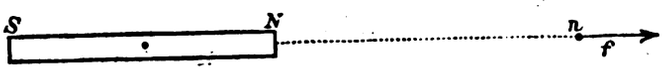

FIG. 83.

the two poles of the magnet act oppositely on the unit pole, the nearer pole (N) having the greater effect, and exerting a force of repulsion equal to $\frac{m}{r^2}$ dynes on the unit pole.

The other pole (S) acts with a force of attraction equal to $\frac{m}{\mathrm{R}^2}$ dynes, and the net or resultant force acting at n will be the difference of these two, viz.:—

$$\frac{m}{r^2} - \frac{m}{\mathrm{R}^2},$$

this being also equal numerically to the intensity (f) of field at the point. The *direction* of the resultant is *from* the magnet in a line with its axis in the diagram. If the magnet were reversed the *direction* of the resultant would be reversed, its intensity remaining the same.

Now,

$$r = d - \frac{l}{2},$$

and

$$\mathrm{R} = d + \frac{l}{2}.$$

Putting these values in the enumerator of the above, we obtain, after cancelling,

$$f = \frac{2\,m\,l\,d}{r^2\,\mathrm{R}^2},$$

where $m\,l$ is the moment (M) of the magnet. Therefore,

$$f = 2\,\mathrm{M}\,\frac{d}{r^2\,\mathrm{R}^2}.$$

Example.—What is the strength of field at a point on the continuation of the axis of a magnet 30 centimetres (d) from its centre, length of magnet 20 centimetres, and pole strength 900 C.-G.-S. units?

Moment of magnet $= 900 \times 20 = 18{,}000$ units.
Distance from nearer pole (r) $= 30 - 10 = 20$ cms.
" " further " (R) $= 30 + 10 = 40$ "

Hence,

$$\text{Intensity of field} = 2 \times 18{,}000 \times \frac{30}{20^2 \times 40^2}$$

$$= \frac{36 \times 3}{64} = 1{\cdot}68 \text{ C.-G.-S. units.}$$

Similarly, we may arrive at an approximate value of the field by a little simpler process (when the point is distant from the magnet many times its length) by reducing the formula to the form (by substituting the values of r and R and reducing by simple algebra)

$$f = \frac{2\,\mathrm{M}}{d^3\left(1 - \frac{l^2}{4\,d^2}\right)^2}$$

Digitized by Google

from which it is evident that when d is great compared to l, the quantity within the bracket approaches unity, and we have

$$f = \frac{2M}{d^3}.$$

Example.—What is the strength of field at a point situated 2 metres away from the centre of the magnet in the last example? Here we may adopt the approximation, as the quantity in the bracket is close upon unity, and we have

$$\text{Intensity} = \frac{2 \times 18{,}000}{(200)^3} = \cdot 0045 \text{ C.-G.-S. units.}$$

(To be continued.)

SIR WILLIAM THOMSON'S NEW STANDARD ELECTRICAL MEASURING INSTRUMENTS.*

Sir WILLIAM THOMSON said the general principles and many of the details of the instruments placed on the table for the inspection of the meeting were already well known, having been described in the electrical journals. It had been considered, however, that the members of the Society might like to see some of the instruments themselves, and to have a few explanations, which he would be able to give personally, regarding details that had not

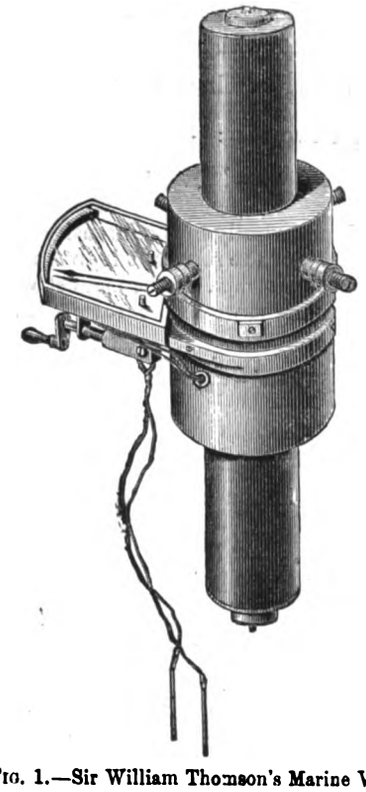

FIG. 1.—Sir William Thomson's Marine Voltmeter.

hitherto been published; and that was his reason for bringing before the Society a subject of which so large a part had been already published, and was known to members of the Society. All the instruments which they saw on the table, except the magneto-static "galvanometer," or current-meter, fell under the designation of standard electric measuring instruments. All these standard instruments, except one, were dependent upon Ampère's discovery of the mutual action between fixed and movable parts of an electric circuit. The one instrument which he excepted was the portable marine voltmeter or milliampere-meter. That instrument, as it stood before them, was a milliampere-meter, but with the addition of resistances wound on the tubular guards surrounding the stretched wire it became a voltmeter. This resistance amounted to about 930 ohms of platinoid to render the instrument a voltmeter for range from 90 to 120 volts. He should take this instrument first, as it was an exception to the others, and say a few words about it.

* Address delivered by Sir William Thomson before the Society of Telegraph-Engineers and Electricians, May 24th, 1888.

The magneto-static current-meter he introduced as an adjunct to the standard instrument, because it was exceedingly useful in extending the scale above and below the range of any one of the standard instruments. Two instruments of the magneto-static species, with one of the standard instruments, gave the means of measuring currents through the whole range, from one milliampere up to several hundred amperes.

He should briefly describe the marine voltmeter (Fig. 1) before passing on to the other standard instruments. He was sorry to say that he should not be able to let them see the interior of the instrument, but he might tell them that he had a type fulfilling exactly the description he should give of this, but with somewhat improved mechanical details, in which, by removing a screw, he could take out the works and let them be seen.

This instrument consisted of an oblate of soft iron suspended on a stretched platinoid wire in the centre of a solenoid. [The speaker here sketched on the board the type of an instrument that was being made in Glasgow.] He said that in this type the bobbin was double and divided for convenience, and the sketch showed two half bobbins, which, he said, could be put together with great ease. One of them was taken out to let a fine platinoid wire pass down through the centre carrying a little oblate of soft iron. The instrument before them was constructed with a single bobbin, and had therefore other details more complicated which he need not now speak of, because he should abandon them altogether. He felt confident that he should not adhere to the type of single bobbin, considering the much less simplicity which it involved in the more delicate and vital part, namely, the suspension of the oblate and the index-needle; which in the new form would be lighter and better adapted for working at sea, and less liable to damage from rough usage that it might experience in carriage on shore. To explain the principle of the instrument he reminded them that a long bar of soft iron (as Faraday had shown) tended to place its length along the lines of force in a uniform field

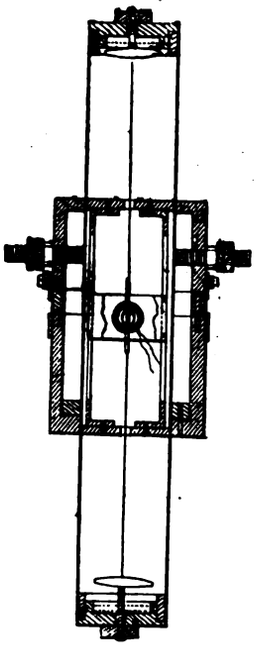

FIG. 2.—Section of Voltmeter.

of force; an oval and a flat disc tended to place its equatorial plane along the lines of force. But he (the speaker) had to choose between an egg shape and an oblate; and he found that an oblate was better for his object. The tendency of the oblate to place its equatorial plane in the direction of the lines of force of the solenoid was the force due to electro-magnetic action, which was balanced mechanically in the use of the instrument (Fig. 2). The principles on which he was led to the choice of this configuration of iron depended upon the circumstance that when they used not excessively high force in the magnetic field, so that the magnetisation of the iron should be very much short of magnetisation, a figure of a short character in which no one diameter was more than twice as long as any other diameter was much less disturbed by magnetic retentiveness than an elongated figure. In an instrument of this class the electro-magnetic force was very nearly in exact proportion to the square of the current, which is rigorously the law of the ampere-force used in—and in that respect it bore very much resemblance to—the gravity balance instruments by which the highest possible accuracy is to be attained. On the other hand, in instruments of the class to which Ayrton and Perry's ammeter belongs, the force was more nearly in *simple pro-*

Digitized by Google

portion to the strength of the current, owing to the iron being used nearly in a state of saturation. The resultant action between the wires conveying the current, and the oblate with its equator oblique to the lines of force was a couple; and that couple was balanced by torsion of the stretched platinoid wire on which the oblate was suspended. The platinoid wire was kept stretched to about one-third of its breaking weight by two springy arrangements at its two ends. These mechanical details would no doubt be interesting to some of the members of the Society, for they were all scientific enough to know that consideration of details was the very essence of success in practical work. The elements of electrical and mechanical science—rudimentary drawings of pumps, levers, springs, solenoids and magnets—were valuable; but a pump without physical science in the packing of its piston would be useless; and in an electrical instrument the elastic, the electric, and the magnetic properties of all its parts must be considered if it is to do good duty, whatever its purpose. And really the perfecting of mechanical details was the life work of any one engaged in practical science.

He just wished to point out a difference between the instrument he was exhibiting and the type that was now being made. In the instrument shown to them there was a latent zero, and unless he turned the torsion head he could not verify the zero. The range of the instrument was essentially limited as it stood now. It ran from 90 volts to 120 volts. It was impossible to make this very satisfactorily *a long range* instrument, except by adjustable resistances, for a reason that he should presently explain. The needle was not allowed to come to the zero at all, and his reason for that was that it was only so that he had been able to eliminate practical error from change of zero in copper wires and platinum wires, which he had used until latterly, when he had adopted platinoid. The elasticity of fine platinoid wire he had found so good that the latent zero during a year's use of the instrument had not changed one-fifth per cent. in its effect on the indication of strength of current. There was, in fact, no sensible variation whatever. He then took the twist out and verified the zero and replaced the twist. He then resolved to give the instrument a visible zero—that is to say, to let the needle regularly come to zero when the current is stopped.

A million years hence the earth would have a very different gravitation force, but this wire would be constant; and actually at the present time gravity differs notably in different parts of the earth, being one-half per cent. less at the equator than at the poles. This portable marine instrument was purely intrinsic, and more constant for all time and place than any other. Gravity was the most constant force they had to deal with practically, but looking at the elasticity of metal, and looking forward some millions of years, the elasticity of a piece of metal was more perennial than gravity. But either elasticity or gravity might be considered as practically quite perfect as to perennial constancy, provided that the weight or spring was not altered by rust or rubbed down or wasted away by evaporation. The marine voltmeter was really a standard instrument of a conveniently portable kind. The platinoid-wire spring had proved most satisfactory. If, after being first mounted and stretched, and heated up to the temperature of boiling water, they knocked the instrument down roughly on its side, or kept it lying on its side for a considerable time, they found that the knocking about and rough irregular usage did not alter the indications at all. And if more rough usage, or long continued rough usage, such as rattling it over paved streets in a cab, should alter the indications, they had the ready means of adjusting the zero at any moment, and so absolutely reinstating it as a standard instrument. The two things to make it so were the constancy of that oblate and each of these pieces of platinoid wire. These were constants which might be regarded as practically absolute, so that generation after generation that little instrument would be a standard current-meter (applause).

This instrument had not yet been much used at sea. He had not pushed it forward, because he had been anxious to satisfy himself about some of the mechanical details; but an instrument exactly like the one before them had been used in one of the State Line ships (the "State of Nevada"), and had made five or six voyages between Glasgow and New York. In the first four voyages it saved breakdowns from over-incandescence estimated at about 40 lamps, and from that time forward the consumption of lamps had been considerably less.

The other standard instruments shown to the meeting were founded on the mutual ampere-force between movable and fixed parts of a circuit. He should take these instruments beginning with one adapted to the smallest currents: they were the centi-ampere, the deci-ampere, the deka-ampere, and the kilo-ampere balances. The range of the centi-ampere balance (Fig. 3) was from one to fifty centi-amperes; the next instrument was the deci-ampere, which was exhibited on the table. The centi-ampere and the deci-ampere were quite similar in appearance, the difference being entirely in the fineness of the wire in the coils. The instrument before them might be taken as representing the deci-ampere, or the centi-ampere, but the type which was being made now differed somewhat from the type before them. The type would not be improved by the difference if used solely for currents in one direction; but if for alternating currents, the copper bobbins on which the wire was wound, and the thick, double sheet-copper sole-plate of the instrument before the meeting would, by the currents induced in them, interfere very seriously with the indications. With reference to the deka-ampere meter, its range was from 2 to 100 amperes. The instrument which he exhibited was a type of those made for Sir Coutts Lindsay and Co., for the Grosvenor Gallery installation, supplied at the request of Mr. Ferranti, and a considerable number of such instruments were provided for that installation. The deci-ampere meters and the deka-ampere meters had been made for the purpose of being available for alternate as well as for direct currents, and therefore they had a slate base, and slate cores, and slate ends for the coils instead of copper; but in other respects the arrangements were the same as in the instruments exhibited. The movable and fixed parts of the circuit in these instruments consisted of two movable coils, one carried at each end of a balance, and four fixed coils, one above and one below each movable coil. The movable coil at one end was attracted down by the coil below it and repelled down by the coil above it, and *vice versâ* at the other end. They had two movable and four fixed coils in this type of instrument. There was an advantage in having the whole six coils that could not be obtained with anything simpler. They might take away the two upper and leave only the two lower coils; but a slight change in the ligament or the beam would induce a sensible error

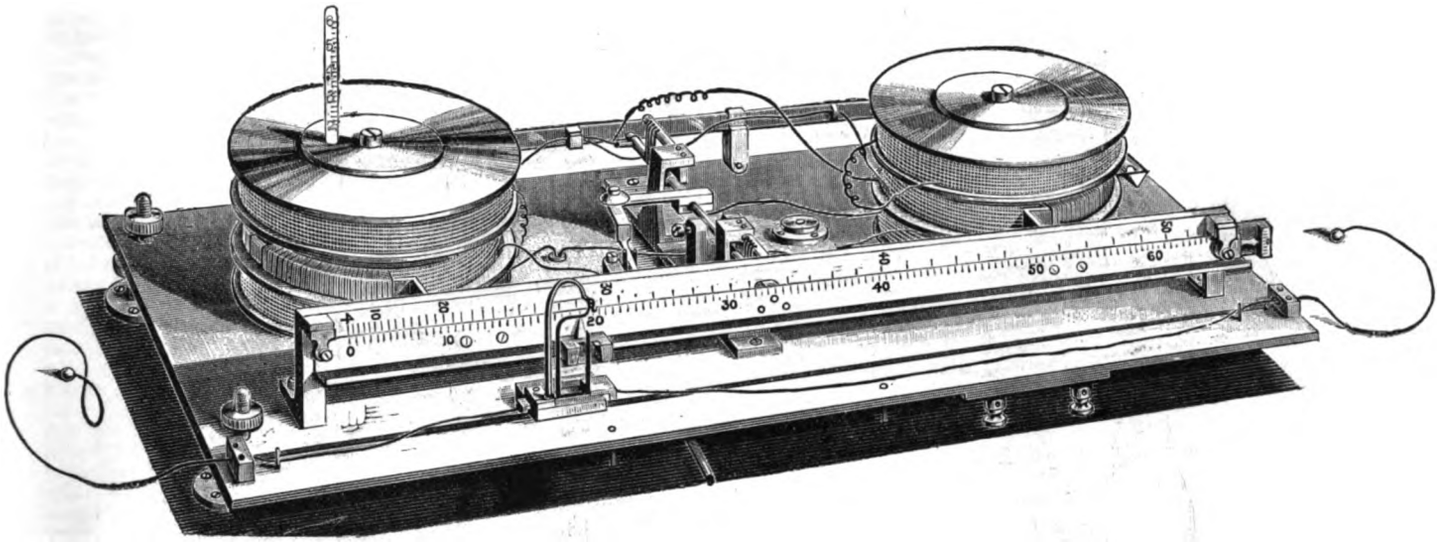

FIG. 3.
SIR WILLIAM THOMSON'S CENTI-AMPERE BALANCE.

Digitized by Google

in the instrument. They had a minimum force for the middle position of each movable coil between two fixed coils, and by choosing the sighted position of the index to correspond very nearly to the place of minimum force they had a condition of things suited to give the highest degree of accuracy in the results. As to portability, his ambition had been that boxes from White's workshop containing his instruments might be labelled "Glass, without care—any side up" (laughter). That was the ideal, but though they were still somewhat far from having attained the ideal, this instrument might actually be turned upside down without taking any harm. Still they might have a mischance. One of these instruments labelled, as usual, "Glass, with care—this side up," had arrived at its destination broken; and it was returned to Glasgow with the lever arms bent and other bad damages, which were clearly owing not to breakdown of the suspension ligament, but simply to the instrument having been thrown on the stone floor of a foreign Custom House. The arms were re-straightened and the balance re-suspended, and everything replaced simply by the instrument maker. It was sent to my laboratory to be re-standardised, and the result was that it was found correct to within one-twentieth per cent. of what it had been before it met with the accident giving that very disintegrating extent of rough treatment. As to the resistance and number of turns of the coils, in the centi-ampere balance, of which the range was from one to fifty centi-amperes, each movable coil contained 440 turns of No. 30 copper wire; resistance 20 ohms; four fixed coils each of 1,295 turns of No. 26 copper wire, resistance 30 ohms; total resistance of the instrument, 160 ohms. That was a large resistance, but to have a standard instrument for measuring such small currents he did not see any way of avoiding doing it without a large resistance. In the deci-ampere balance the total resistance was only two ohms; the deci-ampere balance had a great advantage over the centi-ampere balance. Although founded on exactly the same principles, there was in the deci-ampere balance a far smaller proportion of space occupied by insulation, and a far larger proportion of space occupied by copper in the vital parts of the instrument, and thus a much more than proportionately small insulation, if they calculated on the proportion of dimensions on the idea of the different instruments being similar. They were not similar, because the insulation was thicker in proportion because of the fine wire. In the deci-ampere balance the movable coil was 64 turns of No. 17 copper wire; resistance, ·18 of an ohm; the four fixed coils, each one 66 turns of No. 17 copper wire; the resistance ·428 of an ohm in each, and the total resistance of the instrument 2·072, say 2 ohms. He had passed over the ampere-balance. The ampere-balance was before them; it was not adapted for the measurement of alternating currents, but an instrument slightly less advantageous could be made for alternating currents. The range of the ampere-balance was from ½ to 25 amperes. The ampere-balance exhibited was of the newest type. It consisted of two movable coils, each ten turns of copper ribbon 1·2 centimetre broad, and ·1 thick; 4 fixed coils, each 37 turns of copper ribbon 1·8 centimetre broad and ·07 thick. The insulation of these coils was very fine paraffin paper, so that it took exceedingly little space. As to the hekto-ampere balance, there was in it one point of importance with reference to the very highest accuracy, and that was the complete and thorough realisation of the minimum principle. In this they had a single rectangular ring of copper, movable, and a fixed ring of copper below it. The fixed ring consisted of ten turns of copper. In the kilo-ampere (Fig. 4) balance the range was from 50 to 2,500 amperes, and the fixed coil was made up exactly as in the hekto-ampere balance, with this difference, instead of insulating paper they were soldered together and thus formed a ring. There was great difficulty in getting a forging or casting of copper of those dimensions. The first ring was made from a forging of copper, and they had to wait a long time for it, and he found, at all events for the present, it could be made more easily and with greater certainty of satisfactory results by winding up a ribbon which gave the coil of the hekto-ampere balance.

[Here Sir William Thomson sketched diagrams on the blackboard of the kilo-ampere balance and the hekto-ampere balance, and explained their working.]

In these and all the other balance instruments the beam was supported by two ligaments, each composed of a large number of short pieces of fine copper wire. Besides bearing the weight, these ligaments had to convey the current from a fixed to a movable conductor. He had first tried bearing ribbons of thin sheet copper, and he had found it exceedingly unsatisfactory from the buckling of the ribbons. As he had not succeeded in getting a good result from an elastic bearing of broad ribbon; he had divided the ribbon into narrow bands, and ultimately into thin wires. For the lightest ligament they had about ten very fine copper wires, and for the different types of balance twenty and thirty, and so on up to 900. The number of wires in each ligament of this kilo-ampere balance was 800. The ligament was not to be seen, because there was a strengthening guard, which was fixed across the middle of the instrument, covering the ligament, and guarding it against any chance of injury from rough usage. To make this instrument portable a piece of brass was slipped in beside the ligament, and two screws were screwed down, by which the whole weight was taken off the ligament and the beam held perfectly firm.

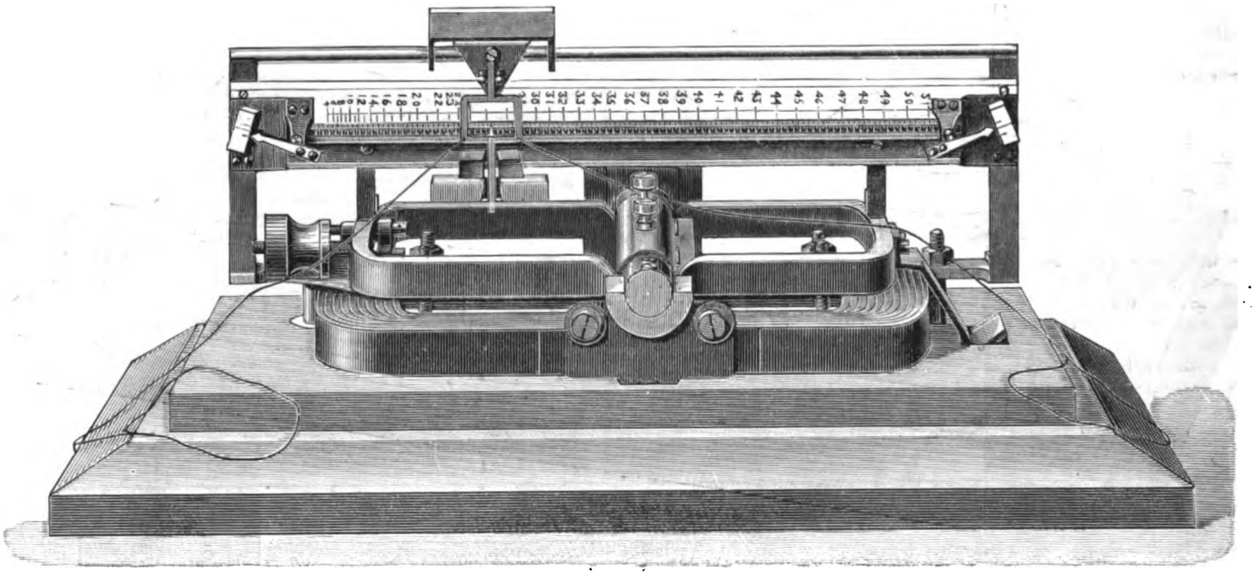

FIG. 4.

SIR WILLIAM THOMSON'S KILO-AMPERE BALANCE.

[Sir William Thomson here made a sketch on the black board of the ligament and strengthening guard.]

They had on the table before them a set of instruments capable of measuring continuously, each adjustable by comparison with the one below it, through a range of from one milliampere up to 2,500 amperes—a ratio of 2,500,000. It was very convenient to have absolute standard instruments through so wide a range; but most people would be satisfied with much less range of *standard*. For a large variety of laboratory and practical uses a deci-ampere balance, ranging from one to 50 deci-amperes, with a milliampere and a deka-ampere magnetostatic instrument to extend the range of accurate measurement down to a milliampere and up to 50 or 100 or 200 amperes, would be found very convenient as an equipment for measuring currents with perfect readiness and sureness from a milliampere up to 200 amperes.

DISCUSSION.

Sir WILLIAM THOMSON concluded his Paper amidst great applause.

The PRESIDENT then said the lecture had been highly interesting, although it was not one that admitted of discussion in the ordinary sense; but there were several gentlemen who might desire to ask questions.

Mr. W. H. PREECE said there were few members present that night who could boast of the experience he could narrate to them. It was his

Digitized by Google

good fortune a good many years ago to have acted as assistant to the great and immortal Faraday in carrying out his classical inquiry into the lateral induction of underground wires. More than thirty years ago he first learnt how to use a differential galvanometer, for the purpose of exact measurement of resistance, designed by Dr. Werner Van Siemens, and made by the house of Siemens. Later all his experience had been acquired by instruments made by Sir William Thomson. Now, they were singularly fortunate in having in that room two of their great fathers in the art of exact measurement. They had there at that table Dr. Siemens, whose presence they greeted (cheers). These were the two philosophers who had taught them all how to measure with precision and accuracy the electrical phenomena with which they dealt practically. They had heard from Sir William Thomson the vast and the wonderful range of these instruments of precision. Many engineers imagined that when they could measure a millionth part of a millimetre by means of a microscope, and when they could judge the distance between the earth and the sun with their telescopes, that their instruments extended over an enormous range; but their range, combined with accuracy, was not to be compared with the accuracy with which electricians could measure from the ten-millionth part of a milliampere up to 25,000 amperes. And, again, not only had they got this enormous range and this great exactitude, but they had that confidence and that knowledge that, under the guidance of Sir William Thomson, they had instruments that imparted in their minds the most express and most explicit confidence. There was no engineer who could say with the same feeling of security and the same firmness of purpose that his measurements were right as electricians could who used the instruments before them. It was, he thought, Mr. Samuel Smiles who stated that attention to details was at the root of human progress. They had learnt from Sir William Thomson that attention to details had been his guiding star through all his scientific career. They were extremely indebted to Sir William Thomson for the clear and able discourse he had given them.

Dr. SIEMENS said that he was in the very unfortunate position of not having had sufficient opportunities of speaking English to enable him to do justice to the kind way in which they had received his name.

Prof. AYRTON said that he had not had any actual experience of the charming instruments they had seen before them that evening, therefore it was impossible for him to say anything about them in detail. But what he could say was certainly this: his colleague and himself had been engaged for a long while on the design and manufacture of electrical measuring instruments, and others who, like themselves, had been similarly engaged, knew the extraordinary difficulty that existed in making any one single instrument to approach approximate perfection. The mere idea of an instrument was not very difficult to arrive at, but to make that instrument a working apparatus was attended with an enormous amount of difficulty. If there was all that difficulty in getting success with one, what difficulty must there not have been to get success with the vast range of instruments before them that evening. He might say that it was surprising that Sir William Thomson, with so many claims on his time, should have been able to devote himself almost continuously to perfecting what he had done, and it only made them feel still stronger admiration for his marvellous powers, about which it was almost impossible for any one to say sufficient or to do justice to. He felt, if he might be allowed to say so, as if he were speaking of a being residing in another universe altogether, having powers that they did not quite understand, and could only look at in a reverential way. That was really what he felt that evening and what he had sincerely felt for the last 25 years (cheers). Criticism was out of the question. They might ask questions, but they could not really criticise. One question he would like to ask in connection with the first instrument that Sir William Thomson showed them. Sir William mentioned that he had used platinoid wire. He asked that for the reason that he had used platinoid wire for an electrical instrument for some time, but they had been overcome by its oxidation. He would like to know whether Sir William had been troubled with it, and, if so, what means he had adopted to get over the difficulty. They had been appalled by the vast range of instruments that evening, but they must not forget that this large contribution to electrical measuring instruments was but a very small part of the contribution that had been made by the inventor to electrical measuring instruments; indeed, almost all their delicate electrical measuring instruments were due to the same author. Nobody had used with more pleasure and at the same time with more agony the quadrant electrometer; pleasure because he was able to do with it what could not be done with any other instrument, and agony because of its peculiar habit of getting out of order. The first advantage was in no way destroyed by the second disadvantage. Take an example:—Prof. Perry and he, some years ago, in Japan, measured with the quadrant electrometer the action of paraffin oil on metals, and he was enabled to do this when it was unable to be done by any known chemical test. He might talk for a week, and still not be able to say all that he would like to say of the marvellous inventive power that they had seen that evening, and it was only one occasion of a repetition of the inventive powers which Sir Wm. Thomson had displayed for the last fifty years, not merely in electrical instrument measuring, but almost in every measuring instrument under the sun. There was no single subject to which Sir William had given his attention, even for a short time, in which he had not left his mark, and left that mark very firmly imprinted (loud applause).

Prof. FORBES wished to ask a question. There was a water tube provided in the voltmeter for preventing dangerous chances of short circuit in connecting this with very high potential mains or circuits. He had noticed that with a high-potential alternating current the voltmeter did not act when this water tube was in.

Sir WILLIAM THOMSON said that Prof. Forbes' observation was communicated to him, and he (Sir William) ascertained that there was no doubt whatever that the Professor's interpretation of it was correct, namely, that the water did not afford a sufficiently rapid electrification to allow this to give the correct mean potential when applied to an alternating-current circuit, and in these circumstances he merely substituted thin wire and let the instrument take its chance of internal contact. They must take care that there was not an electric contact, because this wire guard was not sufficient. He thanked Prof. Forbes for giving him an opportunity of saying that the instrument was now supplied with wire and not water.

Prof. ADAMS joined with Mr. Preece and Prof. Ayrton in admiration of Sir William Thomson's work. They were always exceedingly thankful to him for bringing out a new instrument, although, perhaps, for some of them, they came pretty often (laughter); but at the same time they liked to see the result of the good work if they could not buy it themselves.

Dr. FLEMING agreed with Prof. Ayrton that criticism regarding these beautiful instruments was altogether out of the question. He was, perhaps, fortunate in being able to contribute his own small quota to the discussion in stating that he had had experience in using these instruments, and that he had been privileged to hear from Sir William at various stages of the progress which he had made in perfecting the various types of these instruments during their evolution. For the past two years he had had two or three of those instruments in almost daily use, and he could speak personally of the intense comfort of using an instrument on which one could place absolute reliance. He had two instruments in constant use; one of these was a deca-ampere balance (1—50 amperes), and the other of a type not represented here, which measured from a small fraction of an ampere to 3 amperes. It gave him the greatest pleasure and gratification to be able to bear his testimony to the wonderful and satisfactory addition to the long list of instruments for which the electrical world was indebted to Sir William Thomson.

Prof. SILVANUS THOMPSON joined in the admiration expressed by the previous speakers. There were many of them who would very much like to have the full range of those instruments in their laboratories, but they could not afford to buy a whole series of instruments. He had been asking when they would get an instrument to measure an ampere correct to to 1 per cent. for half-a-crown, and an absolute ampere-meter that should be correct to the tenth of 1 per cent. for ten half-crowns. When they reflected that they could for half-a-crown get a chronometer that would give a better result than one-tenth of 1 per cent., and that now they could buy a watch that would give a result to the one-hundredth part of 1 per cent. for 10s., why should they have to pay such a price for these electrical instruments?

Mr. JAMES SWINBURNE said that he had missed the mho-ohm drum invented by Sir William.

Mr. W. P. GRANVILLE asked if any provision had been made for any source of error in the instruments in which soft iron was used.

Sir WILLIAM THOMSON, in reply, said: Prof. Ayrton asks a question whether I had any experience of platinoid being liable to oxidation. I cannot say that I have found any signs indicating such effect. I do not say that platinoid may not develop that quality of imperfection when tried for a sufficiently long time. It is only a new metal, it being only 2½ to 3 years since it was made. It is a kind of German silver with a very little tungsten added. I have found it remarkably free from oxidation. I tried it in one rude manner as regards oxidation in the new depth-recorder of my deep-sea sounding machine. I use a platinoid spiral spring and platinoid main air vessel, and other chief parts of the instrument, and I have left it between wind and water for months together always moist with sea water. It has shown remarkably little signs of oxidation, and no change whatever as regards the strength of the spring. With reference to the platinoid wire of this marine voltmeter, I have only had it for a 1½-year test, and it has not shown any sign of change, and on the whole I do not expect to find it showing anything of the kind in a thousand years. But that is not a statement which anyone has a right to make except as a probability, and I therefore recede from the assertion that this will last for a million of years, though I believe it will do so (laughter). I used to use platinum, because it may be regarded as absolutely unliable to change by oxidation, but I have found platinoid much more satisfactory as to elasticity. There is one fault of platinoid, and that is that as hitherto supplied, different pieces of the same wire are different, so that in different parts of one wire with absolutely the same gauge you had a sensible difference in resistance. Mr. J. T. Bottomley has found that platinoid varies exceedingly little in its resistance with change of temperature; and, both on this account and on account of its high-class elasticity, it is a material which deserves very careful investigation. The differences of quality between different parts of the same wire may be accounted for by the mode of working the metal in the crucible. Through insufficient mixing in the crucible the ingot may be slightly different in different parts; but that objection is probably only temporary, and platinoid some years hence may be made of practically perfect uniform quality. With reference to the rheostat, which I have omitted to mention, it is not to be taken as an accurate measure of resistance; in fact, as we have just seen, the platinoid wire may be not uniform in its resistance throughout its length. Owing to the freedom from oxidisability of platinoid this platinoid cylinder and platinoid wire work much better than the brass cylinder and brass wire of the original Wheatstone rheostat. The improvement of this instrument consists of a tightening-spring keeping the wire stretched, and a fork for guiding it, without any groove on either cylinder. Thus it works in an exceedingly convenient way, and may be turned rapidly and suddenly in either direction. As to the mho-ohm drum, also alluded to by Mr. Swinburne, I am trying all I can to bring it into practical shape, with good hops of an early result, after a serious trial made thirty years ago, and continuous efforts in my laboratory and White's workshop for the last nineteen months. Mr. Granville has asked a question with reference to soft iron, and that opens up very interesting considerations regarding magnetic induction in iron, which I first learned in working in quite another subject—the Flinders bar for the correction of the mariner's compass, so that the

Digitized by Google

compass, if correct in one latitude, may be correct in another; for instance, in the British Channel and the Cape of Good Hope. A large part of the magnetism of the ship is due to the vertical component of the terrestial magnetism, and that portion of the magnetisation is reversed in the southern hemisphere. The object of the Flinders bar is to annul the effect on the compass of that varying part of the ship's magnetism. Flinders 90 years ago placed a vertical soft iron bar before or behind the compass for that purpose, but it did not get into general use. Some persons who wished to improve it tried again and again, and, among others, Mr. James Napier, one of the sons of Robert Napier, the founder of the great engineering firm, and I questioned him about the difficulty. I said, "If that bar gets a kick from anyone's foot when the ship is heeling over (I might have added, particularly if she is on an East or West course), the compass will show a permanent change when she is upright again." He said that was just what he found. The long and short of it was that a long thin bar is exceedingly liable to irregular disturbance. If you take a long bar of iron, of length more than twenty times its diameter (a common domestic poker answers well), and place it vertically, or, better, parallel to the terrestial magnetic force (the line of "dip"), and place a pocket compass near one end of it, you will see splendidly interesting results. First, you will generally find the upper end acts as with "blue magnetism," and the lower with "red." If you invert it very tenderly, you will find that the end which was upper still acts as with "blue magnetism." If, after you invert it, you give it a very gentle tap with the finger, it will instantly change to "red." That will not take place with shorter bars. In trying to bring the Flinders bar into practical use, I simply tried a bar of certain diameter and shorter and shorter lengths, and put it beside the compass, and found whether, striking it with blows of the mallet, I could make a difference in its magnetic effect. When the length of the bar was twenty or thirty times the diameter, then it was very sensitive to the blows of the mallet, but when not more than eight or ten times the diameter I could invert it and make no change whatever, whether I struck it with the mallet or not. I found its magnetism inverted truly according to its position, and it showed no signs of a retentiveness. Under the influence of the feeble magnetising force of the earth a bar whose length is not more than six or eight times its diameter shows no sensible effect of retentiveness in its action on the direction of the compass. I took that principle of shortening the bar in the electric current-measuring instruments of this class. The practical result is that until a current much exceeding the greatest amount provided for is passed through this marine voltmeter there are no signs of retentiveness. If I work from nothing up to 120 milliamperes in this instrument, up and down and with reversed currents, I find no signs of retained magnetism; but a current of two or three hundred milliamperes leaves a large effect of residual magnetism, which, however, is easily shaken out by turning the little reversing key which forms part of the instrument. I have to thank you for the patience and the very kind manner in which you have listened to what I have said.

A cordial vote of thanks was then given to Sir William Thomson. The proceedings then terminated.

TELEGRAPH OPERATORS IN PERSIA.*

It was a wild, barbarous country, about the Turko-Persian border, inhabited chiefly by nomad Koords, and I missed even the occasional welcome company of the Turkish telegraph line. Its disappearance seemed like casting off the last strand of western civilisation. At that time I hardly expected to see another telegraph line until I should reach Japan, my intention being to reach the Pacific through Turkestan and China.

Suddenly one day, when nearing Tabreez, I saw away off on the desert a sight that made me blink and rub my eyes to make sure that it was not a mere optical illusion I was looking at. The deserts of Persia are famous for producing bogus objects—mirages of lakes and waving palms, of lovely castles and similar fascinating scenes; but this time it was none of these. Miles away to the north, seemingly suspended in mid air, was a league-long row of telegraph poles, straight as a die, even as the pickets of a garden fence.

As I drew nearer the line assumed a more definite form. Its marvellous symmetry, I then discovered, was not the enchantment of distance, but a solid reality in English iron, with the name of the contracting firm stamped on the poles, every pole tapering from a circumference of twenty inches at the bottom to six or eight at the top, and across the dead level wastes of the Persian plains set up as evenly and perpendicularly as they might have been in Hyde Park. It is worth noting, perhaps, by the way, that the English always take particular pains to have everything of this kind very superior in the East; it is a perpetual source of wonder and admiration to the natives, a standing advertisement of England's wealth, power and ability to the multitude who have no other way of learning.

From Tabreez I was able to follow this infallible guide into Teheran. Often I could see it stretching ahead of me mile after mile, the poles so even that they seemed not to vary an inch, and disappearing in the heavens at the farther end by the curious legerdemain of the desert. The æolian music of its triple wires as the desert breezes played through them, and the messages flashed past from India to England, from England to India—how companionable it was, that bit of civilisation in a barbarous country, only those who have been similarly placed know.

During my stay in Teheran I became quite intimately acquainted with the staff, not only in the capital, but throughout all Persia. There are many curious and interesting phases of life connected with the telegraph service in such a country as Persia that are unknown here. Its alignment and its working staff represent a narrow streak of western civilisation through all that part of Asia. Men two thousand miles apart, who never saw each other in their lives, are, nevertheless, well acquainted. The lone Englishman at the little anterior control station at Dabeed is kept informed from day to day by his chums at Teheran of the doings of the European colony there.

Teheran, Ispahan and Shiraz are the three favourite stations in Persia. Operators are rewarded for good service by being stationed at these points, or disciplined for misconduct by being assigned to some lonely control station, where the only society is a few ragged villagers, and their station a mere mud hovel. Dabeed, about midway between Teheran and Bushire, is considered the worst station in Persia. The extremes of heat and cold in Dabeed are intense. From many degrees below zero in winter and raging storms like blizzards, it gets so hot in summer that the operator often sits at his instrument up to his chin in a tub of water. None of the cooling appliances that make life tolerable in India are available here.

The Ingliz telegraph-jee is quite an important personage in Persia. Outside Teheran and Bushire he is the sole representative of Europe. He is a sahib, whose salary often exceeds the income of the Persian prince or governor of the town. He has several servants, and keeps the showiest riding horses in the town, vieing in the matter of horseflesh with the local prince, with whom he is always on very good terms. He and the prince invite each other to dinner: not a day passes but the prince comes and smokes a kalian or two in the telegraph thana, and in the evening they sit beside the steaming samovar and smoke and drink tea. The prince sends his friend, the telegraph-jee, presents of fruit, or a pheasant now and then, and when the line inspector comes along and leaves with the Englishman a few bottles of choice Cruiskeen Lawn the prince knows he will not be overlooked.

The mollars and seyuds and khans and leading merchants—these, too, are all friendly, as a general thing, to the Feringhi. He is the one relief from the monotony of daily life to them, a speck of human interest upon which to centre the Oriental curiosity.

It is often a remarkable change for the young Englishman. From an unambitious berth in England, wages a pound a week, he finds himself in a month or two hobnobbing on equal terms with Persian princes, with twice as much money to jingle as the prince, and riding the finest horse in town. In addition to a large salary, inducements are held out to him to qualify himself for preferment. A sum equal to three months' salary is paid him for passing an examination in Persian. Five hundred pounds are offered as an inducement to qualify for services in India. For all these advantages about the only sacrifice he has to make is of a social nature.

Food is cheap and plentiful, and in the larger stations almost everything can be found in the bazaars. Some of the men marry and settle down in the service; they obtain wives from England, or marry the maid servants at the legations in Teheran. One or two have married American women; but by so doing the "telegraph sahib" loses caste, much as a man does out west by marrying a squaw. He loses caste in the estimation of his comrades, the Persians, and also with the Americans themselves at heart, although they consider the capture of a sahib very advantageous.

Everything is now so thoroughly equipped and organised that the telegraph service runs smoothly and efficiently; but this was far from being the case at first. The difficulties were a long way from being overcome when the line was put through. For some years it was almost impossible to keep communication open between Teheran and Bushire. Here for nearly a thousand miles it follows along the greatest caravan route in Persia. The charvadars and camel men regarded the long lengths of nice strong wire strung all along their route almost in the light of a special dispensation of Allah, sent to their favoured country so that they might obtain all the material they wanted from time to time to mend their ramshackle pack saddles, chains and harness, without paying out any money.

All summer long thousands of camels and pack mules are constantly employed along this route, and the caravan people used to render the line well nigh worthless. Whenever anything broke that could be mended with wire, the charvadar would simply shinny up a telegraph pole and help himself. In a day or two, perhaps, something else would fall to pieces; but it mattered little to the charvadar, for an unlimited quantity of good English telegraph wire was always to be had for the trouble of climbing a pole.

Next to the charvadars the wandering tribes were the worst depredators. The nomads of Persia are much given to embellishing their charms of person by means of thick wire bracelets. Copper or silver wire is their preference, but they have no objec-

* From an article in the New York *Sun*, by Mr. Thomas Stevens.

Digitized by Google

tion to bracelets of baser metal, especially if they can obtain them without pay. To stretch a telegraph wire through country was about the same thing as placing a pot of jam where it can be easily reached by a boy. Nomads who had caught on went strutting about the country wearing a wealth of telegraph wire bracelets that made the eyes of their less lucky tribes bulge with astonishment.

Finding that they could be obtained for nothing by merely climbing up the Ingliz poles and hacking off the wire, the popularity of the new style bracelets spread far and wide among the Elianites, Susmanis, and Bactiaris. These unsophisticated children of the desert, for a long time, outdid even the caravan men. Ambitious young nomads thought they saw in the unlimited quantities of telegraph wire an opportunity to largely increase their wealth, and they began to carry the bracelets into the more remote regions as articles of commerce.

All this the English Government stood patiently, hoping that time and the employment of numerous native linemen would eventually put a stop to the depredations. The caravan people, however, finding that they escaped punishment, grew more and more enterprising and aggressive. They were not slow to discover in the thing they found so profitable sources of amusement to boot. They took to shooting at the insulators for wagers and clipping the wires with bullets for sport.

Another form of recreation was to make a mark up near the thin end of the cast-iron poles, and stand off so many paces and shoot at it. They used to gamble on the number of shots it would take to crack the pole, and bring the upper part, cross-trees, wires, and insulators down to the ground. This was, of course, rare fun for the Persians. But for those who had to bring iron poles from England, and pack them on camels hundreds of miles over the deserts, it was not quite so funny.

The English finally had to appeal to the Shah to protect the line. "Very good," said the king of kings, blandly, "it shall be stopped." Orders were sent out to cut off the hands of people who were found wearing telegraph wire bracelets. This had the desired effect, and to-day the telegrah wires are as safe in Persia as in any country.

PERSONAL SAFETY AND HIGH-TENSION CURRENT.*

BY LEO DAFT.

No apology is needed for dwelling upon this subject at length, which is done to some extent as a protest against the flippant manner in which it is frequently treated by persons accustomed to the use of high potentials. It is not by any means an uncommon thing to hear these gentlemen dismiss the subject with the remark that "one of our linemen has frequently taken a current of 1,200 to 1,500 volts without serious inconvenience." The chief danger of remarks of this character lies in the fact that there is at least a grain of truth in them, and that it is quite possible for the assertion to be apparently proved by the production of the man himself with an emphatic reiteration of the statement, probably embellished by a few observations leading the public to imagine that the experience was rather agreeable than otherwise.

Now, as a matter of fact, the actual amount or volume of current necessary to destroy any human organism has never been carefully defined, or it would satisfactorily settle the question of potential. Even if it had been, there are still many elements not considered by the ordinary observer, and rarely by the technical, which tend to modify the conditions to such an extent that a person even slightly acquainted with electrical laws may prove almost anything with the aid of a little sophistry. For example, the lineman, who is triumphantly cited as a case in point, probably underwent the quoted experience with such a small contact-area—that is to say, with merely a finger-tip, or a very small part of the hand exposed to the conductors—as to enormously increase the resistance of the circuit in which he was included, and therefore to limit the current in the manner alluded to in the quotation on page 1. Again, he may, as a lineman or engineman frequently has, have had his hands coated with oil or some better non-conductor, even more effectual than limited area in reducing the fatal flow of current. It is not enough to prove that he may have been safely exposed to these potentials under favourable circumstances since it is well known that under different conditions the result is invariably fatal. It is also necessary to show that they were such in the matter of contact-area and personal resistance as are likely to occur in practice.

A number of careful observations seem to indicate clearly that a current of 0·5 ampere is generally destructive to any human organism, and if personal resistance were always uniform, which is very far from the fact, this would, of course, definitely fix the limit of potential, and none ought to be considered safe which will not permit any properly constituted person to firmly grasp conductors without serious inconvenience. That this can be done with potentials higher than 250 volts by a person of ordinary constitution has never yet been shown, and is extremely problematical; that it certainly cannot be done with potentials much higher than 300 is a matter of daily experience in every electrical manufacturing establishment.

This is not the place to enter into any abstruse physiological discussion, but a few considerations of potential and resistance tend to define within reasonable limits the amount of current which will do serious injury. An exhaustive series of experiments to determine the resistance of the human body, measured from hand to hand under varying circumstances, shows that it ranges between 1,000 and 7,000 ohms, but a safe mean is probably 2,500 ohms, and experiments made with a view of determining the danger-point have shown that a man measuring 2,500 ohms from hand to hand, using exactly the same terminals during the measurement which were afterwards used in the test, could not withstand the potential increased beyond 250 volts. It is therefore evident that while in this case a current of 0·1 ampere was almost unbearable to a vigorous man, the same individual, with merely the tips of two fingers touching the conductor and by consequent diminution of contact-area increasing the resistance of the circuit, of which he formed part, to 10,000 ohms, was only receiving a current of 0·025 ampere. It plainly follows that with the hands firmly grasping the conductors, as in the first instance, a difference in potential of 250 volts had precisely the same physiological effect as 1,000 volts would have in the latter instance, the current in both cases being 0·1 ampere; while to firmly grasp the conductors would probably have been instantly, or at least quickly, fatal, causing by diminution of resistance a flow of current equal to 0·4 ampere.

Herein lies the danger in any attempt at precision, for the same effects may occur—and frequently do occur from different causes—resulting in fatal accident. Thus a man ignorant of the dangerous effects of moisture in reducing personal resistance may handle with impunity exposed conductors while the hands are dry, which would impart a fatal shock just after washing them or when moist with perspiration, and it is just this uncertainty which renders loose statements of the kind above quoted almost criminal where they do not result from dense ignorance.

In conclusion, it should be remarked that the above refers only to continuous currents, not taking into account the effect of alternations or static charges.

The Electrical Crystallisation of Metals.—Mr. H. Warren has recently devised a very simple method of producing metallic copper in a crystallised form by means of electricity. The arrangement consists of a tube, closed at one end by a diaphragm of gold-beater's skin, and suspended in a dilute solution of chloride of sodium. This tube contains a saturated solution of sulphate of copper, the density of which is maintained by having an inner tube terminating in a point, filled with sulphate of copper crystals. A strip of copper foil 3 centimetres by 1 centimetre is introduced into the copper solution and connected by a wire of the same material to a zinc plate, which forms the negative electrode, and which is in contact with the saline solution. After a few hours small metallic copper crystals commence to form on the positive plate, and at the end of a week the copper electrode becomes a bright mass of copper crystals. Silver, antimony, bismuth, magnesium, iron, aluminium, and all the most oxydisible metals can be similarly reduced.

A Captive Balloon Struck by Lightning.—During a storm which burst over the city of Barcelona, the captive balloon in the Exhibition grounds was struck by lightning, the gas burst into flames, and the balloon was totally destroyed.

TO ADVERTISERS.

"The Electrician" offers exceptional advantages to Advertisers. **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to this office.

Advertisements intended for the current issue must be handed in not later than 4 p.m. on Thursday.

TECHNICAL PRINTING.

"The Electrician" Printing and Publishing Company (Limited) beg to inform Electricians and Electric Light Engineers that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.

The Electricians' Directory.

Royal 8vo. Cloth Boards, 3s. 6d. Boards, 3s.

At the end of December in each year is issued The Electricians' Directory and Handbook. *The Directory was established in 1883, and has now attained considerable proportions. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, accompanied in many cases by Portraits.*

THE DIRECTORY FOR 1889 IS IN PREPARATION.

THE CHEESBOROUGH PATENT.

In continuation of our remarks last week on Mr. Justice Kay's judgment in the Edison-Brush law suit it may be useful to add a few words with special reference to its effect on the manufacture and sale of incandescent lamps in this country. First, however, it will be necessary to state precisely what the essential feature of the Cheesborough patent really is; for on this point there seems to be almost as much misconception as on the subject of Mr. Cheesborough's personality. We have already explained, for the information of *The Times* "and others," that the so-called Cheesborough patent was Mr. Cheesborough's only by virtue of his being the English patent agent who secured the American inventor's rights in this country. The real, or alleged, inventors were Messrs. Sawyer and Man; and whatever else may be said for or against their original specification, it certainly described an entirely novel and practical application of a process which had hitherto existed purely as a scientific experiment. The patent, however, which was taken out in 1878, was chiefly occupied with a description of a wonderful and impossible lamp, and in consequence its true value was overlooked or neglected by electrical engineers for a considerable period. It was reserved for another American inventor to

Digitized by Google

make the discovery that, embodied in this complicated and in some respects ridiculous document, there was something worth digging out and rescuing from oblivion. Need we say that the invention became the property of the Edison Company, and that with their customary astuteness they forthwith disclaimed all the rubbish with which the patent was encumbered, leaving themselves the exclusive possessors of a process which it will be hard to beat, and still harder to infringe?

Divested of its redundancies and inaccuracies, the Cheesborough patent became, in fact, the simple description of the now well-known method of preparing carbon filaments by electrically heating them in carbon gas; and as this feature of the patent has been held to be valid its infringement by the Brush Company, who employed a similar method, has now been established. It is notified that the Edison Company are about to appeal on that part of the case decided against them, but it is not yet known whether the Brush Company will appeal on the other point. Probably they will not; and the question naturally arises, how will the electric lamp industry be affected by the reaffirmation of the validity of the patent? We need hardly inform our readers that the value of the process depends entirely on what is known as flashing; and, unless some other means equally successful of giving uniformity to the carbons be discovered, the monopoly will remain with the present owners of the patent. To make lamps without "flashing" is, commercially speaking, not so easy as some people seem to suppose. In the first place it is difficult to make many carbons which are even uniform along their own length, and when this has been done, so that each lamp is uniform in itself, it will be a matter of infinitely greater difficulty to make the carbons so that they are all alike in resistance and surface. When we remember the numbers of small makers who have tried and failed, we can realise what a very troublesome business lamp manufacture really is. Nothing is easier than to make one lamp or half a dozen lamps; but it is quite a different matter to make a thousand lamps all alike as regards resistance. Even with flashing this was difficult; without it it will be still more difficult. We can imagine the Brush Company or Messrs. Woodhouse and Rawson overcoming this difficulty; but we think the small makers, with less experience, will find this a very hard task indeed.

The future of incandescent lamp manufacture, and with it the future of electric lighting, depends very much on the policy now pursued by the Edison-Swan Company. There has been a rumour in the City that they were going to reduce the price of lamps to three shillings retail. This is very much to be desired. If the Company are wise they will use their victory in such a way as to deserve it. By improving the quality of their lamps, and by lowering their price, the Company may hold their own against all competitors. But, on the other hand, if they seek to command the market on the mere strength of the Cheesborough patent, the probable consequence will be that either the lamp trade will become a prey to cheaper and inferior processes—which would do as much damage to the Edison Company as to the electric lighting generally—or else some equally good process will come to the front that will beat the old method out of the field. Of one thing we are pretty sure, the present price of lamps cannot long be maintained; and the best way to ward against competition will be to forestall it. It is known that lamps can be remuneratively made and sold at a shilling a-piece. Surely it would not be unreasonable to ask of the Edison Company to supply them at eighteenpence, if not just at present then in the not far distant future.

Probably much will be done in the manufacture of high-power incandescent lamps, and it is possible that they may replace arc lamps in many cases. Certainly they are costly to buy, but their maintenance is very much less than that of the arc lamp, giving not the same nominal power on the photometer, but the same amount of useful light in a large building, or even in the street. These large lamps are used very much in America, and they are gradually coming into use in this country. We believe there is no difficulty in making them, but makers did not put them into the market before because there seemed to be little demand for them.

Whether lamp manufacture will waken from its present state of apathy and produce 200-volt lamps, or lamps that will burn for long periods at half a candle per watt, remains to be seen. We wish there were more uniformity of practice among electrical engineers. It would certainly be worth while, if it could be arranged, that incandescent lamps should be made of a few kinds only. For instance, one ordinary run of lamps might be made to give 16 or 8 candles, and to take 40 or 80 volts. We take 80 as the higher limit advisedly. Of course, as far as leads go, the higher the electromotive force the better, but high-resistance lamps are not so durable, so a mean has to be struck. 100-volt lamps are in fashion, but we have been told by practical lamp makers that there is a great fall off in durability and facility of manufacture when 80 volts are exceeded. The 40 or 50 volt will probably be used extensively with transformers, while the 80 volts are better adapted for direct lighting, where the leads are longer.

We would also like to see engineers agree to use, say, 1,000 volts or 2,000 volts on the primary circuits, and 40, 50, or 80 on the secondary circuits, in alternating-current systems, with, say, 10,000 alternations per minute. The Americans, who have had plenty of experience, use 1,000 volts and 50 volts, and a high rate of alternation, but as English engineers prefer smaller speeds for their machines, we think 10,000, which is used in the Grosvenor Gallery installation, more suitable. We do not, however, wish to dictate, hardly to suggest, the best figures; but we do want electricians to agree among themselves, and to work together for the good of electric lighting. These questions will doubtless be discussed, amongst others, in the Electrical Section of the Chamber of Commerce, which now seems in a fair way to be realised.

C. A. BELL'S WATER-JET TELEPHONE TRANSMITTER AND SYSTEM OF TELEPHONIC COMMUNICATION.

BY G. W. DE TUNZELMANN, B.SC.

A Paper was communicated to the Royal Society in May, 1886, by Mr. Chichester A. Bell, M.B., on "The Sympathetic Vibrations of Jets,"* containing an account of some very interesting observations, some of which led to the invention of the water-jet transmitters. It is well known that a jet of water issuing from a narrow orifice gradually becomes discontinuous and breaks up into drops, as shown in Fig. 1, which is taken from an instantaneous photograph. Fig. 2 shows a jet of water from a tube fixed to a board, falling on a membrane of stretched India-rubber forming a cap to a brass tube, which can be raised or lowered by sliding in a larger tube resting on a heavy stand. The upper tube has an orifice at one side of the upper end to which is attached a vulcanite trumpet. Mr. Bell found that with this apparatus either mechanical or sound vibrations communicated to the jet could be reproduced with great loudness and distinctness. The loudness and distinctness both increase up to a certain point when the distance of the membrane from the orifice is increased. After passing this point the sound still continues to increase in loudness while losing its distinctness, until ultimately it becomes a mere un-

* See *Electrician*, June 4th, 1886, p. 80.

Digitized by Google

musical roar, and it will then be found that the jet has become discontinuous above the membrane.

I have shown this myself as a lecture experiment, and when the board to which the jet is attached was scratched with the finger, or when a watch was held in contact with the jet tube, the sounds produced were loud enough to be heard throughout a room containing several hundred people.

FIG. 1.—Instantaneous photograph of a water jet

FIG. 2.—Apparatus for showing the production of sound by communication of mechanical or acoustic vibrations to a jet.

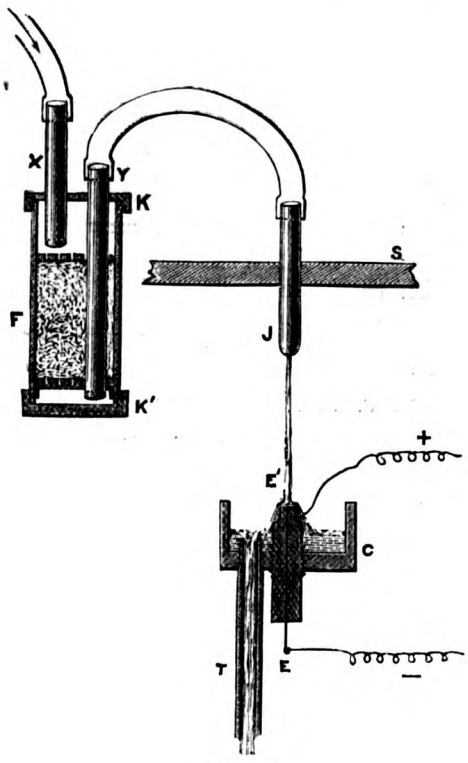

FIG. 3.

Experimental form of Jet Transmitter.—J, jet; S, sounding board; E E', ebonite plug and electrodes; C, ebonite cup; T waste tube; F, filter; K K', screw caps; X, supply tube; Y, exit tube.

The jet tube need not be in contact with the board for the latter experiment, but for the audible reproduction of sound it is necessary to have the tube rigidly attached to a board, to act as a sounding-board, but whether parallel or at right angles to it does not matter. If the jet is spoken or whistled to, it is visibly thrown into vibration, and when attached to a sounding-board the sounds are distinctly reproduced.

If the jet is allowed to fall upon a narrow vertical rod, as shown in Fig. 2, it spreads out into a nappe. Mr. Bell found that this nappe was capable of responding to vibrations in a similar way to the jet itself, and it is this property which is utilised in the construction of the water-jet transmitter.

The principle of the instrument consists in including the nappe of a jet of conducting liquid in a circuit traversed by a current from a battery, and containing an ordinary telephone. The nappe formed by the impact of a steady jet retains a constant diameter, but when thrown into vibration it undergoes periodic changes in diameter—and therefore also in resistance—which Mr. Bell considers to be due in part to the changes in diameter, and in part to changes in the contact resistance arising from the motions of the particles of liquid; so that the current passing through the circuit undergoes corresponding continuous variations in strength, as in other forms of telephonic transmitters. The simplest way of passing a current through it consists in allowing the jet to strike normally upon the exposed end of a platinum wire embedded in an insulator which is impervious to, and is unaffected by, the liquid employed, and surrounded by a platinum ring which comes in contact with the outer portion of the nappe.

The most suitable liquid consists of water acidulated with about $\frac{1}{300}$th of its volume of pure sulphuric acid. It is of special importance that this should be free from lead.

The battery must be of high E.M.F., but its resistance is of little consequence, owing to the high resistance of the transmitter. A battery of about twenty small zinc-carbon cells charged with a solution of sal ammoniac gives very good results with the liquid described, but the number of cells may be increased with advantage; not, however, to such an extent as to sensibly electrolyse the liquid, as the noise produced in the receiving telephone by the escape of gas bubbles would drown the sounds due to vibratory changes in the jet. The pressure required increases with the size of the jet, and with jets of the most suitable size a pressure of a little under three feet of water gives the best results. A simple experimental form of apparatus is shown in Fig. 3.

The jet-tube J is mounted in the sound-board S. The receiving surface is formed by the end E' of an ebonite plug. A platinum wire, E, passes water-tight up the plug, and its upper exposed surface forms the inner electrode of the transmitter. The outer electrode E' consists of a small tube of platinum foil concentric with the upper extremity of the wire E, and is insulated from it by the ebonite. After it has been fitted on, the top of the ebonite plug is turned off so as to present a smooth continuous surface, slightly convex. Fine platinum wires welded to E and E' serve to connect them with the terminals of the circuit. C is an ebonite cup which supports the plug and receives the waste water which escapes through the tube T. F is a filter, closed by screw caps K and K'. Through the upper cap pass two tubes X and Y, which are connected with the reservoir and jet respectively by means of *black* India-rubber tubing. Two perforated ebonite discs are fitted within the cylinder, and the space between them is lightly packed with coarse cotton, which has been freed from grease by soaking in a solution of caustic potash, and been thoroughly washed with dilute sulphuric acid and water. The filter is necessary to keep back particles of dirt which might stop the orifice, and also air-bubbles, the presence of which sets up vibrations and gives rise to a crackling sound in the receiving telephone.

I have made some experiments with an instrument of this kind, but with the jet tube pressed laterally against the sound-board, which was about a quarter of an inch thick, and was fixed in a vertical position. It reproduced with perfect distinctness the voice of a person speaking in the tone of ordinary conversation at a distance of 20 feet from the instrument, and when standing in a room with an open window it reproduced the sounds of a piano played in a room, also with a window open, at the opposite side of the street. On another occasion I succeeded in obtaining an exceptionally clear and pure reproduction of the voices of four boys singing in unison in a room

Digitized by Google

in which the transmitter was placed. When an automatic Edison chalk-cylinder receiver, which had been kindly lent to me by the United Telephone Company, was used in place of an ordinary Bell telephone good results were also obtained.

This form of apparatus is, however, not suitable for practical work, as in addition to its requiring separate vessels to act as reservoir and to receive the waste liquor respectively, it requires careful adjustment whenever it is to be used.

A great many forms of apparatus have been devised for this purpose, and some of them are described in the specification of the patent which was taken out in 1886, and which covers the whole principle of the apparatus. It has been acquired, as far as the American rights are concerned, by the American Bell Telephone Company. It is only quite recently, however, that the inventor has succeeded in devising an apparatus which combines simplicity and certainty of action with durability.

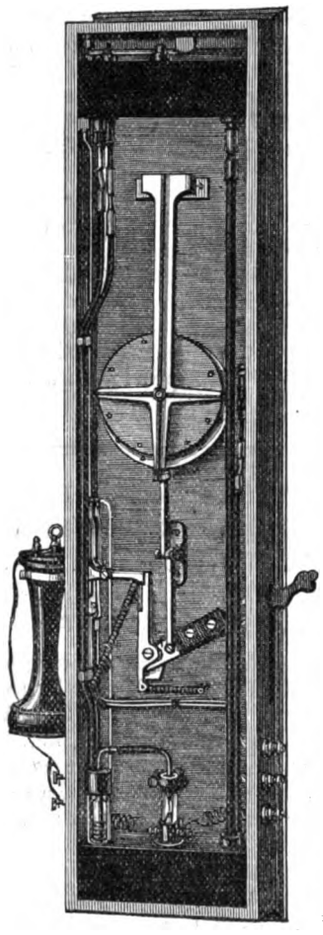

FIG. 4.

Practical form of Jet Transmitter

Fig. 4 shows the instrument with the front removed, and Fig. 5 shows the transmitter and filter on an enlarged scale.

The whole apparatus is enclosed in a case of teak or mahogany about three feet high, and is protected in front by a cover which opens on hinges, and is provided with a lock and key. There is a round aperture, protected by crossed copper wires, opposite the transmitting jet, and in using the instrument the mouth of the speaker is placed at a distance of a few inches from this aperture, as it is neither requisite nor desirable to have a jet as sensitive as that of the experimental apparatus previously described.

The electrodes in this instrument are formed of a platinum wire passing up the centre of a glass plug and a concentric ring of fine platinum wire, glass being used instead of ebonite, on account of its being found more durable. The jet and plug are contained in a glass tube attached to a wooden box resting on the bottom of the case, which receives the waste liquid. The glass plug is rigidly fixed in a vertical position, and the jet is centrally adjusted over it by means of the four screws shown at the upper and open end of the containing tube. The filter is seen on the left hand side of the jet, its exit tube has its extremity enlarged into a bell, which contains the cotton, and the fibres of this are prevented from passing into the narrow part of the tube by means of a piece of cotton material placed at the top of the bell. The reservoir consists of a second box, similar to the first, placed at the top of the instrument, and is filled by taking out a screw plug in the centre of its upper side and pouring the liquid in through a funnel.

The terminals of the receiving telephone are connected with the two left-hand binding screws, the lower one of which is connected to one electrode of the transmitter, and the upper one to a pair of springs which make contact with the lever from which the telephone is suspended, when the latter is removed and the supporting hook allowed to rise. The other electrode is connected with the lowermost of the three binding screws on the right, which is put to earth through the battery; the central right-hand binding screw is in permanent connection with the lever supporting the telephone, and with the line, while the uppermost one is connected through the call apparatus to the line, and also with a spring which makes contact with the telephone lever when the telephone is hung up.

To speak through the instrument the telephone is taken off, but the hook end of its supporting lever is prevented from rising by means of the vertical lever shown: The handle on the right-hand side of the case is now depressed, when a pin on its lower end draws back the vertical lever and allows the telephone hook to rise, placing the telephone in circuit with the line.

The telephone lever, in rising, pushes up a brass rod hinged to it, thus lifting the left-hand end of the lever above the reservoir, and opening a valve, which allows the fluid in the reservoir to flow down an ebonite tube on the left hand side into the filter. A second ebonite tube passes from the filter and opens into the top of the reservoir to allow air to escape immediately, if the filter has run partially dry from the instrument remaining unused for some time. The depression

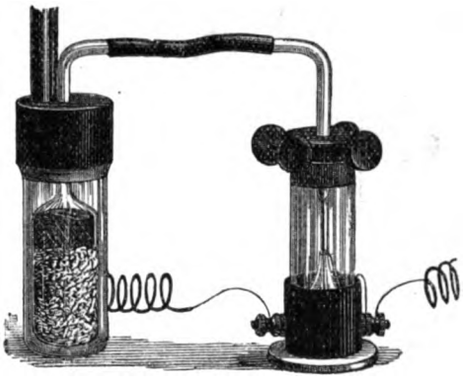

FIG. 5.

Jet and Filter of Practical Instrument

of the right-hand lever at the same time compresses an India-rubber bag, shown in the centre of the case, and drives air into the lower box through an ebonite tube seen on the right hand, which is provided at its upper end with a valve opening inwards, and forces liquid from the lower reservoir through the other ebonite tube on the right hand into the upper reservoir.

The amount of liquid pumped up by one depression of the lever is sufficient for about seven minutes' conversation; and as the average length of a conversation would in general be less than this, there will usually be enough liquid in the upper reservoir to allow of a longer conversation as often as it is likely to be wanted, without pumping up fresh liquid; which, however, does not interfere in any way with the conversation being carried on.

The object of the control lever, which keeps the telephone out of circuit until the right-hand lever is depressed, is to prevent users from forgetting to pump up a fresh supply each time.

Digitized by Google

The instrument is chiefly valuable for use on trunk lines over long distances, as any leakage on the line can be compensated by using additional battery power, and very good results have been obtained with it on lines upwards of 100 miles in length, and passing through six or eight exchanges, and therefore subject to a considerable amount of leakage.

In general four Leclanché cells are sufficient.

The system of telephonic communication devised by Mr. Bell is intended especially for use with the water-jet, or any other form of high resistance transmitter that may be invented, and its principal advantage is that it does not require the use of any batteries except at the exchange.

With the transmitter now in use it is not practicable in the case of lines of any length to transmit speech by the direct action of the vibration of the transmitter in varying the resistance of the line-circuit, and therefore an induction apparatus is used, the transmitter being placed in the primary, and the line in the secondary circuit, and this involves the use of a battery at each sub-station.

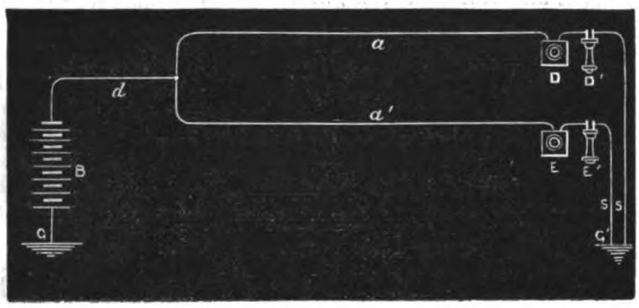

FIG. 6.

Diagram explanatory of Bell System of Telephonic Communication.—B, battery; *d*, connecting wire; *a a'*, line wires; D E, transmitters; D' E', receivers; S S, earth wires; G G earths.

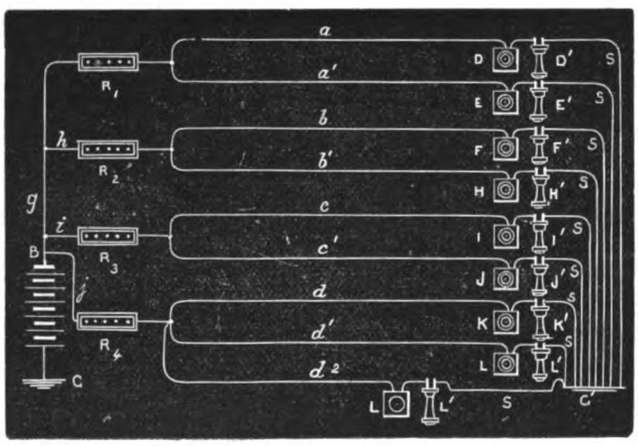

FIG. 7.

Bell system of telephonic communication. B battery, G G' earths, S earth wires *g h i j* connecting wires, R_1 R_2 R_3 R_4 resistances, *a a' b b' c c'* line wires connected in pairs, *d d' d*$_2$ three line wires connected in a group, D E F H I J K L transmitters, D' E' F' H' I' J' K' L' receivers.

Consider the arrangement shown in Fig. 6, which shows a battery, B, of high E.M.F. and low resistance put to earth at G, and connected with a line, *d*, which divides into two branches *a* and *a'*, which contain the transmitters D and E and the receivers D' and E', and are then put to earth at G' through the wires S S. Vibrations communicated to either transmitter will not be communicated to the receiver at the other station, because the earth connection through the battery forms a low-resistance shunt. If, however, a suitable resistance, R_1, is inserted in the branch *d*, as shown in Fig. 7, this will no longer be the case, and it is easy to make the resistance R_1 so large that practically the whole disturbance originated at D is transmitted to E', more cells being added to the battery, if necessary. The inventor has found experimentally that in the case of short lines (such as ordinary town lines) the resistance R_1 may be varied from about 2,000 to 8,000 ohms without appreciably affecting the action of the transmitter, supposing the jet transmitter to be used, the resistance of which is about 1,000 ohms.

In practice it is desirable to make the resistance R_1 adjustable, as it may then be varied as may be requisite to compensate for leakage in the lines due to hygrometric variations.

If the stations D and E were connected directly through a battery at the central station a battery of twice the E.M.F. would be required to give equally good results, as has been proved to be the case by experiment. Further, if the two stations are connected directly through the central battery, and the transmitters are of unequal resistance, the speaker at the low-resistance end will not be heard so well as the one at the high-resistance end; but this is not found to be the case when the connections are made as described.

A single battery can be used for all the subscribers to one exchange, if desired. Thus, Fig. 7 shows two additional pairs of subscribers using the transmitters F and H, and I and J connected through the resistances R_2 and R_3 and the wires *h* and *i* with the wire *g* from the battery to R_1, and it is found that each pair can carry on conversation without interfering with, or being overheard by, any of the others. The connection can, of course, be varied by means of a switch-board, as in the ordinary system.

Fig. 7 also shows a group of three transmitters connected through the lines *d*, *d*$_1$, and *d*$_2$, the resistance R_4 and the wire *j*, with the central battery. In this case a speaker at one transmitter, K, for example, will be heard in the receivers L L' at both of the other two stations.

At an ordinary telephone exchange a battery with an E.M.F. of 30 to 40 volts would be required, and it should have large plates. A battery of about 20 medium-sized secondary cells answers admirably; but any battery which does not run down on open circuit may be used, provided its resistance does not exceed a few ohms.

INFLUENCE OF THE CHEMICAL ENERGY OF ELECTROLYTES UPON THE MINIMUM POINT AND CHANGE OF POTENTIAL OF A VOLTAIC COUPLE IN WATER.*

BY DR. G. GORE, F.R.S.

By means of a zinc platinum voltaic couple in distilled water, with its electromotive force balanced by that of a suitable thermo-electric pile† (*Proc.* Birm. Phil. Soc., Vol. IV., p. 130), the effect of several groups of chemical substances upon the potential of the couple was examined. Measurements were made of the electromotive forces of a series of strengths of solution of each substance, and the results are given in a series of tables.

The minimum proportions of substance required to change the potential of the couple in water were as follows:—

Potassic iodate	between 1 in	433 and	494
,, bromate ...	between 1 in	344 and	384
,, chlorate ...	between 1 in	221 and	258
Potassic iodide	between 1 in	15,500 and	17,222
,, bromide.....	between 1 in	66,428 and	67,391
,, chloride.....	between 1 in	695,067 and	704,540
Iodine	between 1 in	3,100,000 and	3,521,970
Bromine	between 1 in	77,500,000 and	84,545,000
Chlorine	between 1 in	1,264,000,000 and	1,300,000,000

On comparing these numbers we find that the proportion of substance required to upset the voltaic balance was largest with the oxygen salts, intermediate with the haloid ones, and least with the free elementary halogens. It was smaller the greater the degree of chemical energy of the substance; thus it was about 400 times less with chlorine than with iodine. And it was smaller the greater the degree of freedom to exert that energy; thus it was about 5,416,000 times less with free chlorine than with potassic chlorate, or 1,570,000 times less than with the combined chlorine of the chlorate, and about 185 times smaller than with potassic chloride, or 88 times less than with the combined chlorine of that salt.

* Paper read before the Royal Society, June 14, 1888. Abstract.

† This instrument is manufactured by Messrs Nalder Brothers, Horseferry-road, Westminster.

Digitized by Google

The order or curve of variation of potential by uniform increase of strength of the solution was different with each substance, and was apparently characteristic of the body in each case. A great number of such representative curves might be obtained with a zinc platinum or other voltaic couple in different electrolytes.

THE LONDON CHAMBER OF COMMERCE.

The following important circular has been issued by the London Chamber of Commerce :—

ELECTRICAL AND ALLIED TRADES SECTION.

Botolph House, 12, Eastcheap, London, E.C.,
24th July, 1888.

Dear Sir: It has been suggested that, with a view to the direct and effective representation in the London Chamber of Commerce of the Electrical and Allied Trades, a Section (or Committee) should be formed in connection with that body. In order that nothing should be done in this direction without the general concurrence of all concerned—whether members of the Chamber or not—you are invited to attend a preliminary meeting, at which the proposal will be considered, at the offices of the Chamber, as above, on Friday next, the 27th July, at 3 p.m. The fullest discussion is invited, and if it is considered desirable to form the Section, resolutions in that sense will be submitted, and its organisation proceeded with.

The special advantages of organising under the auspices of the Chamber of Commerce are, that the Chamber is already in possession of suitable premises and staff, under which the necessary work of the Section can be adequately performed; time will be spared to members in preparing bye-laws and other regulations of procedure; whilst no financial responsibility is involved beyond payment of the entrance fee and subscription to attain membership of the Chamber; nor is it necessary even for members, in case they are not satisfied with the management of the Committee, to continue their membership or subscription, as enrolment in the Chamber does not involve more than an annual subscription, which can always be terminated by a month's notice prior to the expiration of the current year. The formation of the Section in connection with the Chamber would in every way, therefore, be less costly and at the same time more effective than if it were attempted to form a separate Committee apart from the Chamber, which would have to rely upon its own resources.

The proposed Electrical and Allied Trade Section, if formed, would not interfere with the work of existing Associations, but would only deal with matters that are purely commercial. The Section, in fact, would be an integral part of the London Chamber of Commerce, a body composed of over 2,500 members engaged in almost every kind of trade and industry. No less than 18 Trade Sections, formed within the Chamber itself, are directly represented on the Council by their own delegates, in addition to 17 of the leading Mercantile Associations in London, and it is intended to give the same right to the remaining branches of commerce. It is, therefore, felt that so important an interest as that of the electrical and allied branches should not remain without direct representation, and this may be secured by the formation of an Electrical Trade Section, or Committee, whose chairman would possess a seat on the Council of the Chamber, to whom he would submit for confirmation all resolutions, reports, or recommendations adopted by the Section. Action would then be taken in the name of the Chamber itself.

Amongst the matters with which it is suggested that the Section might deal may be mentioned Bills before Parliament, Foreign Tariffs, Treaties of Commerce, Customs Classification, Arbitrations (for which the bye-laws of the Chamber provide), Business Extensions in India and the Colonies, Electric Lighting Legislation, Fire Insurance Rules, Telephone and Telegraphic Matters, &c., &c. On these and other subjects, the recommendations which the Section could make to the Council would be of special value, and the influence of the Chamber with the Government Departments, with Parliament, with Provincial and Colonial Chambers of Commerce, and public bodies generally, would greatly assist in carrying them out. It is also thought that professional, as distinct from commercial, men, would be brought—through the Section—into closer contact with the commercial community in regard to all matters where they have mutual interests.

At a meeting of those interested in Electric Lighting, held on Friday last, the gentlemen whose names on the other side are marked with an * joined the Chamber for the purpose of becoming members, and strengthening the representation of the proposed Section.

I am, Dear Sir,
Yours faithfully,
KENRIC B. MURRAY, Secretary.

LIST OF THOSE INTERESTED IN THE ELECTRICAL AND ALLIED TRADES WHO ARE ALREADY MEMBERS OF THE LONDON CHAMBER OF COMMERCE :—

ALABASTER (H.), GATEHOUSE & Co.
ALLEN, J. (F. Allen and Sons).
*ALLPRESS and BELSHAW.
ANDERSON BROS.
ANDERSON, J. H. (Anderson, Anderson and Anderson).
ANDERSON, SIR JAMES, Director Eastern Telegraph Company (Limited).
ANDREWS, W. S., Managing Director Indo-European Telegraph Company (Limited).
ANGLO-AMERICAN TELEGRAPH COMPANY (Limited).
ANGUS, GEO., and Co.
APPLEBY, C. J. (Appleby Bros., Limited).
BELDAM, A.
BEWICK and MOREING.
*BIGGS, C. H.
*BLACKBURN, A. B., Director Edison and Swan United Electric Light Company (Limited).
BINSWANGER, G. (G. Binswanger and Co.).
BOLLING, F. (Bolling and Lowe).
BRABY, F. (Fredk. Braby and Co., Limited).
BRAND, J., Chairman United Telephone Company (Limited).
BROOKE, C. B. (Phelps, James and Co.).
BROOKER, E. G. (Brooker, Dore and Co.).
BULLIVANT, W. M. (Bullivant and Co.).
BURROUGHS, S. M. (Burroughs, Wellcome and Co.).
BURT, J. H. (J. H. Burt and Co.).
CADIOT (E. H.) and ESPIR (F.).
CALLENDER and SONS.
CANNING, Sir SAMUEL.
CHURCHILL, J. D. (Durham, Churchill and Co.).
COOPER, Sir DANIEL, K.C.M.G., Chairman Electrical Power Storage Company (Limited).
COURTENAY, J. I., Managing Director Electrical Power Storage Company (Limited).
*CRAWFORD, Earl of, Chairman London Electrical Supply Corporation (Limited).
CROMPTON, R. E. (R. E. Crompton and Co.).
*DOWSING, H. J. (R. E. Crompton and Co.).
DAVIES, Capt. W. H., Managing Director Exchange Telegraph Company (Limited).
DENNIS, W. F. (W. F. Dennis and Co.).
DORE, S. L. (The Blackwall Galvanised Iron Company, Limited)
*DRAKE and GORHAM.
DRAPER, GEO., Secretary Eastern Telegraph Company (Limited).
DUNCAN, J. H. (J. H. Duncan and Co.).
EASTERN TELEGRAPH COMPANY (Limited).
*ERSKINE, R. S. (Kensington Court Electric Light Company, Limited).
EARLE, C. W., Chairman West India and Panama Telegraph Company (Limited).
ELLIS, B. P. (J. Aird and Sons).
FELL and WILDING.
*FELLS, J. M., Assistant Secretary and Accountant Anglo-American Brush Electric Light Corporation (Limited).
FIRTH, THOS. and SONS (Limited).
FRASER, G. C. (Fraser and Fraser).
GARCKE, EMIL, Manager and Secretary Anglo-American Brush Electric Corporation (Limited).
GRAY, ROBT. KAYE, Chairman Spanish National Submarine Telegraph Company (Limited).
GREWING, H., Chairman Telephone Company of Austria (Limited).
HAROLD, H. C. (Harold and Jenkins).
*HEAPHY, MUSGRAVE (Phœnix Fire Office, Limited).
HENLEY'S (W. T.) TELEGRAPH WORKS COMPANY (LIMITED).
HILL, PEARSON.
HODD, R., jun. (R. Hodd and Son).
HOGG, QUINTIN (Hogg, Curtis and Campbell).
HORNSBY, RD. & SONS (LIMITED).
*IMMISCH, MORITZ (Immisch and Co.)
INDO-EUROPEAN TELEGRAPH COMPANY (LIMITED).
JACKSON, Col. R. RAYNSFORD, Chairman National Telephone Company (Limited).
JOHNSON, J. G. (Johnson and Sons).
JOHNSON, MATTHEY and Co.
JONES, W. E. (Bayliss, Jones and Bayliss).
KIRK (WHEATLEY), PRICE and GOULTY.
*LAING, WHARTON and DOWN.
LOEFFLER, J. C. L., Chairman Siemens Brothers and Co. (Limited).
MACGREGOR, ALEX.
MANCHA, J. DE, Chairman Cuba Submarine Telegraph Company (Limited).
MAXIM, H. S.
MERRYWEATHER, J. C. (Merryweather and Sons).
*MORDEN, W. M. (Anglo-American Brush Electric Corporation, Limited).
*MOUNTAIN, M., General Manager Gülcher Electric Light Company.
ORIENTAL TELEPHONE COMPANY (Limited).
PENDER, Sir JOHN, Chairman Eastern Telegraph Company (Limited).
PREECE, W. H. (General Post Office).
*RAWORTH, JOHN S. (Anglo-American Brush Electric Light Company, Limited).
*REEVES, F. R. (R. E. Crompton and Co.).
*ROBINSON, MARK H. (Willans and Robinson).
*SNELL, W. H., *Electrician*.
*THOMPSON, A. (Thompson and Ritchie).
TRENCH, Col. the Hon. W. LE POER, R.E., Director Edison's Indian and Colonial Electric Company (Limited).
*TROTTER, A. P.
TWEEDDALE, The Marquis of (Eastern Submarine Telegraph Company, Limited).
TYRER, THOS. (May and Baker).
VOELCKER, Dr. AUG. and SONS.
VON GLEHN, ERNEST (Ragosine and Co.).
*WALLACE, ROGER (Kensington Court Electric Light Company, Limited).
WARNE, WM. and Co.
WATT, HUGH, M.P., Chairman Maxim-Weston Electric Company (Limited).
*WEBBER, Major-Gen. C. EDMUND, R.E., C.B.
WELLCOME, H. S. (Burroughs, Wellcome and Co.).
WILLIAMS, E. PASCOE (Merryweather and Sons).
WOODHOUSE and RAWSON.
WRIGHT, J., Secretary Maxim-Weston Electric Company (Limited).

THE LIGHTING OF THE ADELPHI THEATRE.

The Adelphi Theatre, which was re-opened on the 19th inst., is now lighted throughout by electricity. The generating plant, which is sufficient for 4,000 incandescent lamps, has been supplied by the Edison and Swan Company, and is placed in a building below the street level at Bull Inn-court, adjacent to the theatre. The Adelaide Gallery, the Strand Restaurant, and other buildings are also to be supplied from the same source. It comprises three 156 horse-power Babcock and Wilcox safety-tube boilers, working at a pressure of 140lb. The machines are driven by four of Messrs. Willans and Robinson's double centre-valve compound high-speed engines, two of 75 indicated horse-power and two of 130 indicated horse-power. These engines are coupled direct to four Edison-Hopkinson dynamos, two for an output of 105 volts, 800 amperes, at about 425 revolutions, and two for an output of 105 volts, 475 amperes, at about 475 revolutions. The armatures are of the bar type, and the magnets are exceedingly massive, those of the larger machine weighing nearly six tons. The four sets stand on one solid mass of concrete 6ft. thick, and there is a very marked absence of noise and vibration.

It is anticipated that a very economical result will be obtained, and already at a preliminary trial at Messrs. Willans and Robinson's works, an electrical horse-power in the external circuit was obtained from 30lb. of steam per hour, and a return of 82 per cent. of the indicated horse-power. These results were obtained with comparatively wet steam, and as great precautions have been taken to supply dry steam, still better results should be obtained in practice.

The external circuits will be twelve in number, and two large distributing boards of slate, 6ft. 6in. by 4ft. 6in., have been provided. The connections take the form of large brass bars, which can be coupled by means of plugs, so as to make any number of combinations between the dynamos and circuits. In effecting changes sparking is avoided by shunting the plugs through a quick break switch. The dynamos all work on independent circuits, and one dynamo is always held in reserve, and whenever it has to relieve another already at work any dip in the lights is avoided by first of all bringing it up to full load on a resistance, and then exchanging loads between the two dynamos by the reversal of a commutating switch.

It is Messrs. Gatti's intention in the course of a few weeks to entirely dispense with the gas service throughout the theatre, so far as lighting is concerned. About 1,500 lights are required to light the bars, passages, refreshment rooms, auditorium and stage. The auditorium is lighted from the dome by means of eight 250 candle-power Edison-Swan lamps, which produce an excellent effect. Ornamental three-light brackets are suspended round the tiers, and single lights are fixed in the pit, gallery, and boxes. Duplicate circuits have been provided throughout, and great precautions have been taken with a view to secure absolute safety from fire or possible extinction of the light. The lamps for the floats, footlights, and battens are provided with collars of a special form, each carrying its own cut-out, and having extended terminals making contact directly with the main wires, which are completely enclosed in a slate casing, and on which also the lamp sockets are mounted. Proximity of any combustible insulating material to parts developing heat is thereby entirely avoided. All the other conductors about the stage are enclosed in wood casing. They are strongly insulated with india-rubber, and further protected by a sheathing of asbestos tube, and in all places where there is any liability to injury by violence or by nails being driven through the casing a lining of sheet iron is provided.

Lamps of high candle-power have been introduced in the construction of the variable resistances required for scenic effects.

The whole of the work has been carried out under the superintendence of Mr. Blackburn, Assoc. M.I.C.E., resident engineer to the Edison and Swan United Electric Light Company, to whom great credit is due for the excellence of the arrangements in every part of the installation. It may be added that the work was begun and finished within a period of eleven weeks.

DUBLIN CORPORATION AND THE ELECTRIC LIGHT.

A special meeting of the Dublin Corporation was held on Tuesday last for the purpose of considering and taking action on the following letter of the Board of Trade :—

"GENTLEMEN : With reference to the meeting which took place at this office on the 3rd inst. between the representatives of the Corporation of Dublin and of the Alliance and Dublin Gas Company on the subject of the above-mentioned matter, I am directed by the Board of Trade to inform you that, after a careful consideration of the view expressed by both parties, they propose to proceed with the consideration of the license, subject to the following remarks :—As in deference to the wishes of the Gas Company the Corporation have agreed to a limit of time being fixed within which the contemplated works should be completed, the Board of Trade will not object to the proposed limit of two years and six months being inserted in the license. They are also prepared, as power is sought to supply electricity for public purposes only, to omit the power of transfer now contained in the draft license as agreed to by the Corporation. The question of compensation to the Gas Company for public lighting plant thrown out of use by the introduction of electricity is a matter with which the Board of Trade are of opinion they have no power to deal in a license, and they are therefore unable to insert any provisions for this purpose. With regard to the remaining question in dispute—viz., the area of supply, the Board of Trade do not consider that the reasons advanced by the Gas Company are sufficient to justify this department in restricting the powers sought by the Corporation, for lighting the public streets with electricity, to streets specially named. I am to add that upon hearing that the Corporation agree to the above proposals, the Board of Trade will at once refer the draft license to counsel to settle, and will forward a copy to the Corporation for their observations before it is finally issued.—I am, gentlemen, your obedient servant, "COURTENAY BOYLE."

Mr. ROBINSON said the resolution he had to propose was :—

"*That the conditions contained in the letter of the Board of Trade of July 10th be accepted, and that they be requested to issue a license in accordance with the conditions contained therein. But, so far as the completing of the installation at present contemplated within two and a-half years, the Council desires that the clause of the license should be so framed as to leave it open to the Council to make subsequently such further extensions of this system within the city as the Council may from time consider advantageous.*"

Mr. MAYNE, M.P., objected to a limit of time, as it would involve them in difficulties. They had undertaken to do the electric lighting within two and a-half years, but they did not know what would be necessary to complete it (hear, hear), and he thought the Council should strike against the word "complete."

Mr. DENNEHY said although the Corporation had power to undertake electric lighting, there were difficulties in the way which it would be well for the Council to consider. If it turned out that they were losing £2,000 a year by this electric lighting, each member would be personally liable for it ; and they should also remember that what cost £16,000 to Mr. Mayne and his fellow directors of the late Electric Lighting Company was sold for £3,000.

Mr. HEALY said Mr. Dennehy might make his mind perfectly at ease as regarded financial loss. Nearly every town in America was using the electric light, and in a great many towns in England, and everywhere it was a success, both as an illuminant and financially. There would be no rivalry between the electric light and gas if the gas being supplied to the city went on as it was doing now, increasing in heat and not decreasing in illuminating power ; because it would eventually become invaluable for cooking purposes and everything else.

Alderman DILLON suggested that steps should be taken to have this license extended so as to include private lighting. Some of the residents in Merrion-square had set up installations for private electric lighting.

Mr. MAYNE said it was not in consequence of any financial loss that the Electric Lighting Company had to be wound up. They had made as much profit on their winter lighting as to make up for any loss during the summer. For every sixpence worth of plant that the Company owned they had full business, and they found they should purchase more lamps and additional machines. That stage in their existence happened to arrive at a most unfortunate time, when the possibility of electric lighting had brought a lot of scheming financiers into the electric lighting market, who were swindling the public wholesale ; the house of cards fell down, and people found themselves robbed of enormous sums of money, and nobody would touch electric lighting shares. When this collapse was in full swing they pressed their shareholders for a call, but the shareholders were so frightened that they insisted on winding up the Company, which was the only honest electric lighting company that had been established in the three kingdoms, established for purely commercial purposes, and not for stock-jobbing. Their shareholders were bitterly sorry ever since.

Mr. ROBINSON said that Councillor Dennehy would not be Councillor Dennehy if he did not consistently oppose every reform attempted in the Corporation. The times were progressing, but Councillor Dennehy was not progressing with the times. He begged to move the adoption of an addition to the resolution :—

"*And so far as the completing of the installation at present contemplated within two and a half years, the Council desires that the clause of the license should be so framed as to leave it open to the Council to make subsequently such further extension of this system in the streets as from time to time they may consider advantageous.*"

They had thought that by limiting their application for public purposes it would meet with no opposition from the Gas Company. They thought that at least the Gas Company would recognise the right of the Corporation to light their own streets, yet they have thrown every obstacle in the way by lodging a petition with the Board of Trade, and by opposing it in the Council by their spokesman, Councillor Dennehy. Under these circumstances he thought they were under no obligation to the Gas Company, and Mr. Boyle had stated that taking this license would not prevent them from going for a provisional order in November for private lighting.

After a somewhat noisy scene, provoked by Mr. Dennehy, the resolution was put and carried unanimously.

CONDUCTIVITY AND THE ATOMIC THEORY.

BY W. P. GRANVILLE.

In the year 1863 Prof. Newlands pointed out that many of the physical and mechanical properties of the elements were intimately connected with their atomic weights, and since that time Meyer, Mendelejeff, Crookes, Carnelly, and others have so elaborated this conception that the "periodic law," as it is termed, is now fully established. This law states that "the properties of the elements are a periodic function of their atomic weights"—that is to say, that if the elements are arranged according to the increasing value of their atomic weights their properties are found to be gradually modified as these values increase. This gradual modification is, however, not continuous from the first of the series to the last, but proceeds in alternations or periods having points of maximum and minimum value.

My object in writing this Paper is to discuss in the light of the Atomic Theory the phenomenon of electrical conducl tivity, endeavouring to show that the conductivity of a metadepends chiefly upon the relative number of molecules it contains in unit mass; for, if conduction be the result of some state of induction or polarisation carried on continuously from atom to atom, we can readily see why the metal with the greatest number of molecules per unit mass should have the highest conductivity, because the strength of such an action between two or more bodies depends upon their proximity.

Perhaps the first thing to attract the attention of a student of modern chemistry is the great variation in the atomic weights of the different metals, varying, as they do, from 7 in lithium to 210 in bismuth. At first one would imagine that the metal with the greatest weight per atom would also have the highest specific gravity. But this by no means follows; an atom of cadmium, for instance, has nearly double the weight of an atom of copper, yet, bulk for bulk, copper is the heavier of the two metals. The interpretation of this must be that a mass of copper contains a greater number of atoms than a mass of cadmium—in other words, has greater atomic density. If this be so, we can readily obtain the comparative number of atoms per unit volume by simply dividing the specific gravity by the atomic weight.

The atomic theory divides all the elements into distinct groups, according to their "valency," the theory being that with certain of the elements, such as silver, thallium, potassium, sodium, &c., the atomic construction is simple. These are classed as monads, whilst in other metals, grouped as dyads, triads, and tetrads, the atoms are linked together in twos, threes, and fours, to form molecules, each molecule forming a united whole, or system, having a common centre of action.

In the following table I have grouped according to their valency those metals whose conductivities have been ascertained, and, amongst other data, have added a column showing the relative number of atoms per unit volume, calculated, as before explained, by dividing the specific gravity by the atomic weight, and then, so as to avoid fractions, multiplying by 1,000. The specific conductivity given is the reciprocal of the resistance of one cubic centimetre. By comparing columns A and B, it will be seen that in a remarkable degree (as far as our knowledge extends) electrical conductivity varies according to molecular density, the only variation from this law being with magnesium and mercury, and the conductivity of the latter is greatly affected by its fluidity, for, according to experiments by Cailletet, Bouty and also by C. L. Weber, the conductivity at the point of solidification is increased in the ratio of 4·02 to 1, and whereas in the liquid state the temperature coefficient is very small, they found that in the solid state mercury has the same temperature coefficient as the other metals.

I have purposely omitted from the above list those metals which are strongly para-magnetic, as they seem to form a class by themselves, having approximately the same specific gravity, atomic weight, atomic density, and conductivity. By comparing their atomic densities with those in the foregoing table, it will be seen that the actual conductivity is less than might have been expected. May not a possible reason be that extra work is done by the current, because the phenomenon of magnetism is produced as well as that of conductivity?

	Atomic weight.	Specific gravity.	Relative No. of atoms.	Specific conductivity.
Iron	56·02	7·84	140	101,780
Nickel	58·59	8·9	152	79,365
Cobalt	58·6	8·6	147	106,140

In Table I. I have inserted the dyad metal beryllium because its relative number of atoms greatly exceed that of any other metal, and it would therefore be very interesting to ascertain by actual experiment if its conductivity is proportionally high. Perhaps the extreme smallness of its atomic weight may in a great measure compensate for the large number of the atoms, for lithium, which has the smallest atomic weight of any of the metals, is reported to have a very low conductivity, but on whose authority I do not know.

No doubt the conductivities that have been ascertained are only very approximate, for even with copper, a metal very

Digitized by Google

readily prepared in a pure state, the *absolute* conductivity is open to much doubt, for, as is well known, copper can be now obtained having a higher conductivity than Matthiessen's standard for the pure metal. We can, therefore, well understand that with many of the rarer metals, and particularly those less easily isolated and more readily oxidisable, great errors may arise, as a mere trace of a foreign substance materially affects the result.

SOUTH KENSINGTON.

EXAMINATIONS OF THE SCIENCE AND ART DEPARTMENT.

Honours Examination.

Full marks can only be got by answering all the questions.

41. Describe the apparatus and operations necessary for the determination of the mechanical equivalent of heat by means of observations on the heat developed in a wire when an electric current is passed through it.

Answer. A convenient form of apparatus for making this determination is shown diagrammatically in Fig. 30.

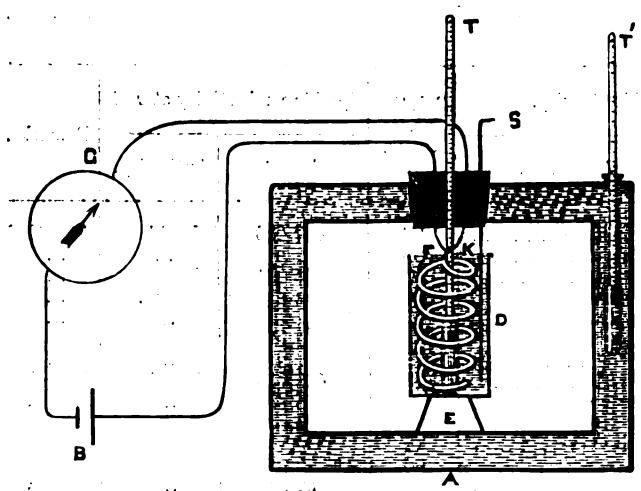

FIG. 30.

B is a battery capable of sending a sensibly constant current through the circuit for a considerable time. Joule found in his experiments that there was no difficulty in maintaining a sensibly constant current for an hour or more. The strength of the current is measured in absolute units by means of the tangent galvanometer G, and when great accuracy is required the value of H, the horizontal component of the earth's magnetism at the position occupied by the tangent galvanometer, should be determined at the time of each experiment. The determination of H may of course be avoided by using some form of electro-dynamometer instead of a tangent galvanometer. Thick copper conducting wires lead from the battery and galvanometer to the ends of a long fine wire of some highly resisting material, such as german silver or platinum, doubled upon itself and rolled into a spiral, the connections being made at F and K by soldering. The spiral is contained in a calorimeter, D, of copper or brass, containing distilled water, and resting on a glass tripod, E, within a metal vessel, A, with double walls, in the space between which a stream of water is allowed to circulate slowly in order to maintain it at a constant temperature. This vessel is closed at the top by means of a cork, through which pass the conducting wires. A stirrer, S, is used to ensure that the whole of the water in the calorimeter should be at the same temperature at the time of an observation, and a thermometer, T, by which the temperature of the calorimeter can be ascertained. The vessel A serves to protect the calorimeter from external sources of heat, and thus ensure a uniform condition in the surrounding temperature throughout an experiment. The constancy of the temperature of the water circulating through A is tested by means of the thermometer T^1.

When a determination is to be made the circuit is closed, and as soon as the current becomes steady a series of readings of the thermometer T are taken at equal small intervals of time, say every four minutes for example, the water in the calometer being stirred in the intervals between the readings, and observations of G and T^1 being made at intervals in order to be certain that both the current and the temperature of A remain constant during the experiment. When the current is turned off readings of T should continue to be taken at the same equal intervals of time, counting from the moment of breaking contact, and these observations should be continued for a time equal to that occupied by the former portion of the experiment, the same precautions being taken to maintain the water in the vessel A at a constant temperature. The last series of observations enables us to determine the loss of heat by radiation, and therefore the corrected temperature readings, namely, the readings which would be obtained if there were no loss by radiation.

Adding the water equivalent of the calorimeter to the mass of water contained in it, and multiplying the sum by the corrected increase of temperature, we obtain the amount H of heat given to the calorimeter during an interval of time t. If C be the strength of the current in absolute units, J the value of the mechanical equivalent of heat, R the resistance of the spiral in absolute units, we have to determine J, the equation

$$J H = C^2 R t,$$

in which, of course, the value given to H must be the mean value obtained from the observations.

42. How would you determine the value of an unknown resistance if you were supplied with a battery, a Thomson's quadrant electrometer, and any wires, keys, or resistance boxes you might require? If the electrometer were not fitted with a replenisher and gauge, how would you guard against errors due to a loss of charge by the electrometer during the experiment.

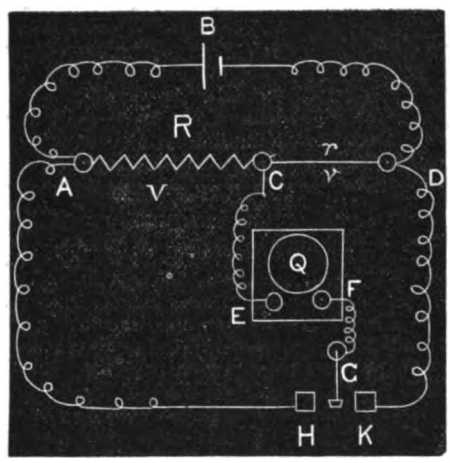

FIG. 31.

Answer. Let r (Fig. 31) be the resistance to be measured, R a resistance box, B the battery. Join up R and r in series with the battery. Let C be the common terminal of R and r, A and D the remaining terminals. Join one terminal E of the quadrant-electrometer Q with C, and the other terminal F to one of the binding screws G of a key. Let the key have two other binding screws, H and K, joined to A and D respectively, and be capable of putting G in connection with either H or K.

First measure v the potential difference between C and D, and then V the potential difference between A and C. Adjust R so that V is nearly equal to v, then R will be nearly equal to r. Then measure the ratio of v to V, which will give that of r to R, for since the current through R and r is the same we must have

$$\frac{r}{R} = \frac{v}{V}.$$

In order to eliminate the effect of a gradual loss of the charge of the electrometer, a series of measurements should be made of v and V alternately, and the mean values taken for substitution in the above equation.

43. Explain exactly how you would determine experimentally in absolute measure the electromotive force of a constant cell.

Answer. Assuming that we have not at our disposal any cells of known E.M.F., in which case we could measure the E.M.F. of the given cell by balancing it against a measured fraction of the E.M.F. of the standard battery, the simplest method depends on the fact that if a known current, C, traverses a known resistance, R, the potential difference E between the terminals of R is given by the equation $E = C R$.

The arrangement is shown in Fig. 32.

R is a variable resistance, P and Q its terminals. B is the given

Digitized by Google

constant cell, B′ a stronger constant battery, G a reflecting galvanometer, T a tangent galvanometer or electro-dynamometer, by which the strength of the current is measured in absolute units, K and H are keys.

The resistance R is adjusted so that when the key K is depressed while the current through B′ is flowing through R, there is no deflection in the galvanometer G.

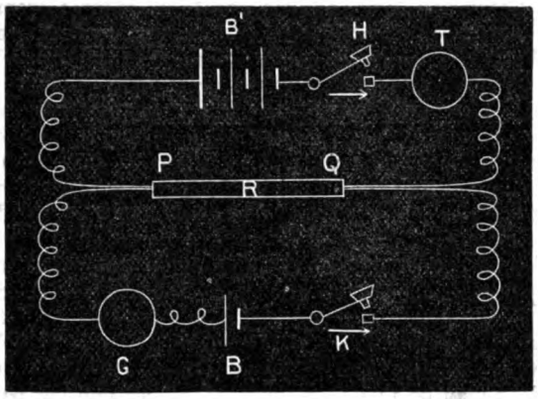

FIG. 32.

If R is measured in ohms and C in amperes, the product will then give the E.M.F. of B in volts.

44. Two metal balls, supported by insulating stems at a small fixed distance apart, are electrified so as to attract each other with force f. If now the balls are immersed in bisulphide of carbon (specific inductive capacity = 2), show what force they will exert on each other :—

(1.) If their respective charges remain the same as when they were surrounded by air.

(2.) If the difference of their potentials is the same as when they were in air.

Answer. Let e and e' be the charges of the same ball in media of specific inductive capacities K and K′. Let V and V′ be the potentials at a distance r from this ball, due to the charges e and e'.

Let f and f' be the forces between the balls in the two cases, and let W and W′ be the values of the total electrical energy of the system of two balls.

Then we have $$V = \frac{e}{K}, \quad V' = \frac{e'}{K'}.$$

Let the ball have equal displacements in the two cases, then the amounts of work done will be in the ratio $f : f'$. But the total electrical energy is the sum of the products of each charge into the potential of the charged body, so that

$$\frac{W}{W'} = \frac{e\,V}{e'\,V'}.$$

But the difference of energy after equal displacements will be in the same ratio, so that

$$\frac{f}{f'} = \frac{e\,V}{e'\,V'}.$$

Hence by substitution we have

$$\frac{f}{f'} = \frac{\frac{e^2}{K}}{\frac{e'^2}{K'}} = \frac{e^2\,K'}{e'^2\,K},$$

or

$$\frac{f}{f'} = \frac{V^2\,K}{V'^2\,K'}.$$

In the case considered in the question K = 1 and K′ = 2, so that when the charges remain the same $f' = \frac{1}{2}f$, and when the potential difference remains the same $f' = 2f$.

45. In an experiment for the determination of the capacity of a condenser by the ballistic-galvanometer method connections were made as follows : The current from a battery of Leclanché cells was allowed to pass continuously through a set of coils of total resistance 11,000 ohms. Then (Fig. 33) the condenser (C) to be measured was charged by joining its coatings one to each of two points in the circuit separated by an intervening resistance of 3,000 ohms ; after which it was discharged through the ballistic galvanometer (G), and the throw was read by the motion of a spot of light on a straight graduated scale ; mean reading, 64·2 scale divisions.

Next (Fig. 34) the condenser was removed, and the galvanometer was joined in multiple arc with a coil of 200 ohms forming part of the battery-circuit, the resistance of the galvanometer-branch being made up to 20,123 ohms. The galvanometer thus showed a permanent deflection of 58·44 scale-divisions.

Time of one complete vibration of galvanometer-needle = 8·452 sec.

Determination of Damping.—The galvanometer-needle having been set vibrating, the first elongation observed was 104 scale-divisions, and the twenty-fourth elongation was 45·5 scale-divisions.

$$\frac{1}{23}\cdot\log\frac{104}{45\cdot5} = \log 1\cdot0366.$$

Distance from galvanometer-mirror to centre of scale = 85·75 cm. 300 scale-divisions = 19·04 cm.

The deflections are so small that they may be identified with their *sines* or *tangents* without sensible error.

Calculate, from the above data, the capacity of the condenser.

Answer.—Let E be the potential difference between the terminals of the condenser = $\frac{3}{11}$ of the E.M.F. of the battery.

Let C be the capacity of the condenser, K the reduction factor of the galvanometer (K = H/G in Maxwell's notation), θ the throw of the needle, T the time of a complete oscillation of the needle, λ the logarithmic decrement, ρ the ratio of damping, Q the charge communicated to the condenser.

We have then

$$C = \frac{Q}{E} = \frac{T\,(1+\frac{1}{2}\lambda)\sin\frac{1}{2}\theta}{\pi\,E}$$

Now $1/n$ of the current will pass through the galvanometer, where n is determined by the equation

$$\frac{200}{20123} = \frac{1}{n-1},$$

which gives $n = 102\cdot125$.

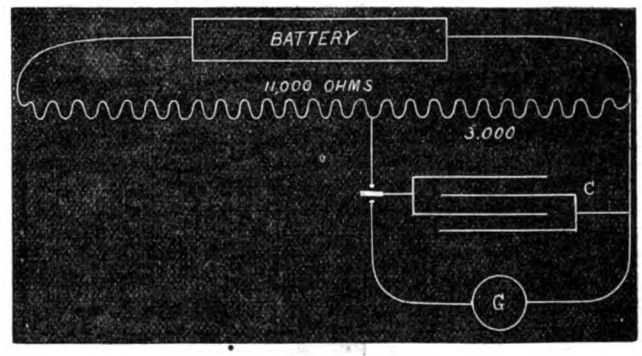

FIG. 33.

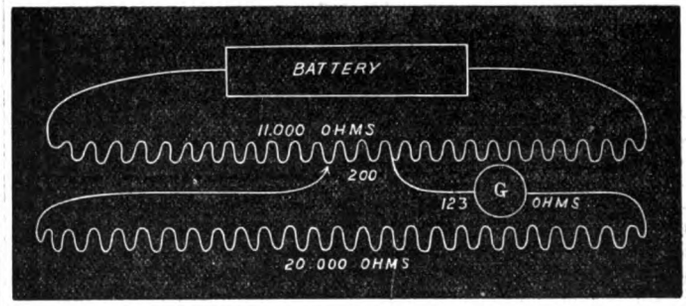

FIG. 34.

Let i be the strength of the current through the principal circuit, ϕ the steady deflection of the galvanometer.

Let r be the resistance between the extremities of the shunt circuit, then we have

$$\frac{1}{200} + \frac{1}{20123} = \frac{1}{r},$$

which gives $r = 197\cdot062$ ohms. Now the battery resistance may be neglected in comparison with that of the rest of the circuit, so that if R be the total resistance of the circuit traversed by the current i we have

$$R = 10800 \text{ ohms} + 197\cdot062 \text{ ohms} = 10997\cdot062 \text{ ohms}.$$

Now we have

$$\frac{\frac{11}{3}E}{R} = i = n\,k\tan\phi.$$

Thus we obtain

$$C = \frac{11}{3}\cdot\frac{K\,T\,(1+\frac{1}{2}\lambda)\sin\frac{1}{2}\theta}{\pi\,R\,n\,K\tan\phi}.$$

Digitized by Google

As the angles are small enough to be identified with the sines or tangents, this expression contains only the ratio of two angles, and therefore the scale deflections may be written instead of the angles.

Again $\lambda = \log \rho$, or $\rho = e^{\lambda} = 1 + \lambda$ approximately,

so that $\frac{1}{2}\lambda = \frac{\rho - 1}{2} = \cdot 0183$ and $1 + \frac{1}{2}\lambda = 1 \cdot 0183$.

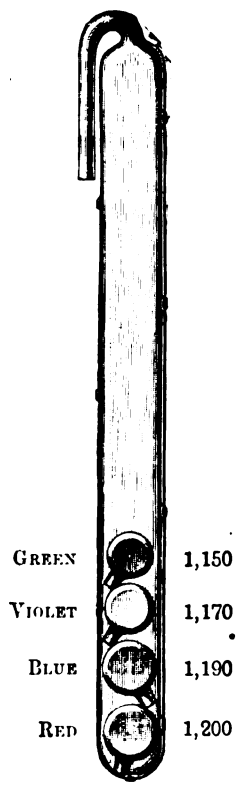
Thus we obtain finally

$$C = \frac{8 \cdot 452 \times 1 \cdot 0183 \times 32 \cdot 1 \times 11}{3 \cdot 1416 \times 102 \cdot 125 \times 10997 \cdot 062 \times 58 \cdot 44 \times 3} \text{ farads}$$

$$= \cdot 0000049127 \text{ farads} = 4 \cdot 9127 \text{ microfarads.}$$

THE HICKS GLASS-BEAD HYDROMETER.

The accompanying figure shows a new pattern hydrometer which has recently been brought out by Mr. J. Hicks (of 8, 9, and 10, Hatton-garden, E.C.), and which will be found to be well adapted for the



rapid testing of accumulator cells. Only a few words of description are needed. The hydrometer as seen in the figure consists of a glass tube pierced at the bottom and on the sides by several holes to admit the free access of the liquid. Within the tube are four small specific gravity bulbs of different colours, placed one above the other, and capable of freely rising and falling in the tube, which they nearly fit. The top bulb, which is coloured green, will float when the specific gravity reaches 1,150, the violet at 1,170, the blue at 1,190, and the red at 1,200. These figures are clearly marked on the back of the tube. Any ordinary workman can be entrusted with the use of this instrument where the reading of a scale might lead to errors.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *July 14th*, 1888.

There has been a great deal of talk in the papers during the past week or two as to the probability of a strike among the telegraph operators. The rumours are not confined to one city in particular, but appear to be afloat in Chicago and Philadelphia, as well as in New York and Boston. One of the prime movers in the agitation is said to be Mr. T. O'Reilly, a bright active man, and a leading spirit of the telegraphers' brotherhood. Mr. O'Reilly is said to enjoy the intimacy of Mr. Powderly, who is at the head of the vast organisation known as the Knights of Labour, with which the telegraphers' brotherhood is affiliated; and, undoubtedly, Mr. Powderly derived much of the material for his campaign in favour of Government telegraphs from Mr. O'Reilly himself. In some quarters it is thought that the present year will be a good one for the strike, from the fact that the Presidential fight, as it warms up, will require constant telegraphic service, and thus render the telegraph companies unwilling to run a risk in any way of losing the large addition to their income from this source. It has been noticed, too, that whenever there is a big strike the Western Union Company forfeits its dividends, and it is held that the company rather than go on doing this would make at least a temporary concession. On the whole the likelihood of a strike does not seem very great. It is true that the salaries of the operators for some time past have had a downward tendency; but the explanation of this is to be found in the fact that the ranks of the operators are overcrowded, and so long as there are large numbers outside the offices waiting for positions, it is not likely that those inside who have reasonable hopes of permanency are likely to chance losing everything. There is a probability that we shall see some agitation on the subject this summer, when the operators will probably try to secure shorter hours at better pay. It is possible that concessions may be made on both sides, as neither party is wishful to repeat the experience of five years ago.

In surveying the present situation in New York with regard to placing the arc light wires underground, one involuntarily ejaculates "Here's a state of things, here's a pretty how d'you do!" The controversy, so far from dying out, has become embittered, and now promises serious trouble. It will be remembered that the Board of Electrical Control forbade the contumacious United States Company to operate certain of its wires. Not satisfied with that, it has now joined hands with the Board of Aldermen in an effort to shut up the company altogether. It is alleged that the original franchise granted to the company did not contemplate overhead wires at all, but merely the laying of the wires underground in tubes. The Board of Electrical Control has further called the attention of the Attorney-General to the points in question, and has requested him to bring a suit to dissolve the United States Company on the ground of its unauthorised construction of its franchise. This means a fight if anything does, as the company will certainly resist such an attack to the bitter end, with all the influence and capital that it can bring to bear. In the meantime the Board has been adopting certain regulations on the advice of its expert, Mr. Wheeler, which will certainly tend to render the operation of overhead wires less dangerous. One of the rules provides that all circuits carrying a current exceeding 500 volts, between 9 a.m. and 4 p.m., must be painted red for a length of two feet at each insulator; and another rule provides that every electric light wire carried on poles shall be indicated by a number plainly marked on each cross arm under the insulator. It is also provided that every circuit must be tested at least once an hour when in operation. The Board has further adopted a form of notice to be affixed to poles, fixtures, &c., which contravene the regulations, giving warning that if they are not made to meet and conform to the rules immediately, the Department of Public Works will be requested to remove them.

In a recent letter I referred to the fact that considerable interest was being taken in the graphophone, and that the instrument, which was being brought forward quite prominently, was found to be very simple and efficient. Further information on the subject is now being contributed by Mr. Charles Sumner Tainter, in an elaborately illustrated article which is published this week by the *Electrical World*. It would appear from Mr. Tainter's statement that the credit of the development of the graphophone is largely his, and that the "improved" phonograph, as it is called, owes its better results in no inconsiderable degree to the adoption of improvements which belong specifically to the graphophone. Mr. Tainter claims, in fact, that at least twenty of the broad claims of the patents on the graphophone are infringed in the phonograph. The great and distinctive feature of the graphophone is that its record is cut or engraved in wax; whereas in the phonograph as brought out by Mr. Edison some ten years ago, and practically un-

Digitized by Google

changed until within the last few months, the record is made by punching or indenting on a sheet of tin foil. While the record engraved on the wax is not susceptible of any change, the indenting method is open to grave criticism, on the ground that each new puncture made by the travelling stylus alters the shape of the one immediately preceding, so that the whole record from beginning to end is inevitably distorted. Mr. Tainter's work dates back to 1885, and his article makes reference to exhibitions of the machine as early as the fore part of 1886. He states that graphophones are now being used in both Houses of Congress at Washington, by the official stenographers as well as by members who dictate their correspondence. One of the machines was recently used in this city by an official stenographer attached to a special commission of inquiry, who immediately after each day's proceedings dictated his notes to the machine, and then left the waxen cylinders for his amanuensis to transcribe for him at leisure next day. It is, I suppose, from the fact that Mr. Tainter's claims to some of the most valuable improvements are justified that we owe the combination which has just been effected here between the phonograph and graphophone interests. It is said that the machines will be placed on the market in a couple of months, when I venture to predict that there will be a big rush for them, as one of the greatest curiosities, as well as one of the most remarkable time and labour-saving devices, of the age.

A great many electrical engineers are deeply interested in the news which reaches us from England as to the intention to make a start in the use of electric motors on the Underground Railway in London. It is believed that the change will effect an enormous improvement in the condition of the road and in the general efficiency of the service; but I hear a great many doubts expressed as to the advisability of adopting storage batteries for such a piece of work, and these doubts are expressed, too, by men who have the firmest belief in the general availability of the storage battery for such work. The great recommendation of the storage battery in connection with electromotive purposes has been that there were very objectionable features in the use of overhead wires or conduit conductors for city traffic, whereas each storage car was a self-contained unit, and did not depend on any external assistance; but in the case of the underground road, American engineers say, there is not the slightest reason why the overhead conductor or the third rail should not be used, and opinion here is generally in favour of the overhead conductor, which would be out of the reach of everybody on such a road, which, it is presumed, could be very effectually insulated. We shall watch this work with great interest, hoping that no irremediable mistake may be made, and that perhaps American electrical engineers may have a chance to lend a hand.

A new electric motor which has been introduced to public notice this week is that of Dr. O. Lugo, who utilises in his machine the maximum effects found in placing moving solenoids in proximity to fixed solenoids, in such a relation that as the armature coils move, the maximum number of lines of magnetic force is cut in the passage of each armature coil past each field coil, these effects being made successively, so that there is a continued application of them. In the motor brought out there are four similar bobbins attached to the shaft of the motor. The revolving armature coils are connected to the commutator fixed to the shaft, upon which bears a stationary brush; while the other side of the armature shaft carries a revolving brush, which bears against a fixed commutator, to which the ends of the field coils are connected. From this arrangement it appears that in every revolution of the armature shaft each armature coil is placed in circuit with each field coil, and there being four of one and five of the other, it follows that there are twenty successive pulls at as many radial positions of the shaft, each pair of coils being in circuit successively only during 1-20th of a revolution of the shaft.* By this arrangement, moreover, Dr. Lugo claims to avoid the evil effects due to self-induction, for the reason that only the minimum amount of effective wire is in circuit at any time. Another feature is that sparking at the commutator is avoided, from the fact that there is no magnetic lead in the field or armature, as the field travels round just in advance of the armature as each bobbin is cut in.

The seventh annual meeting of the Association of Railway Telegraph Superintendents has been held here this week. The object of this association is the promotion and advancement in general of the interests of the telegraphic department of railways, the duties of which, as the proceedings showed, tend every year to become more complex and comprehensive. The association has a membership of close upon 100, including all the leading railroads of the country, and the superintendents themselves are, generally speaking, a highly competent and intelligent class of men, in most cases graduates from the ranks of the operators. One of the subjects which came up for discussion was the distribution of standard time, on which an interesting address was made to the Association by Commander A. D. Brown, U.S.N., who is connected with the Naval Observatory at Washington, which furnishes correct time to all parts of the country. In connection with the distribution of time the observatory has adopted the Gardner system of controlling clocks; and Commander Brown states that they have a line from the observatory to various public buildings in the city of Washington upon which are no fewer than 225 clocks, or, including branch circuits, a total number in operation of about 400. This system has been in operation about four years. The clock is the ordinary eight-day clock, and contains its own motive power. The office of the electric signal is merely to set it, the connection being made by means of an attachment to the clock. When the signal passes the hour, minute and second hands move to zero; in other words, the clocks in Washington show twelve hours, no minutes and no seconds at the exact time that the same is shown by the observatory clock. The railroads have naturally had their attention called to this system, and it is now in use upon some of them, notably the Piedmont-Air line, as it is called.

As Commander Brown remarked, in explaining the details of the system, it must certainly be a great comfort for any superintendent to know that at the instant of noon by the clock of the observatory whence he derives his time, every train despatcher's clock shows the same hour, minute and second. Among the other subjects brought before the Association were the induction system of train telegraphy, electric welding for rails, and the use of the electric light in stations and train yards.

News has just reached this city as I close my letter of the death, at Rochester, N.Y., of Hiram Sibley, one of the fathers of the Western Union Company. Mr. Sibley was of English stock, and essentially a self-made man, starting with nothing, and dying with a fortune estimated at from 6 to 10 million dollars. His connection with the telegraphic business dates back to 1851, when he bought the House patents and built 100 miles of line. A few years later he joined hands with Ezra Cornell, who represented the Morse interests, and from the "pooling of the issues" resulted the Western Union Telegraph Company, which was incorporated under the laws of Wisconsin and New York in 1856. Mr. Sibley was early convinced of the feasibility of a line across the Continent to California, but when he first proposed the scheme to his associates he was met with discouragement, on the ground that failure would damage the new company, and that it was altogether beyond their financial resources. Mr. Sibley told his critics that if they would not join hands with him he would "go it alone;" and go it alone he did, till at last he secured an annual subsidy from Congress of $40,000, and the line was built and finished in 1861. The line immediately became profitable, and was the basis of several fortunes. Such a pronounced success naturally called attention to the work of building a line to connect America and Europe by way of Asia, across the Behring Straits. The plan was actually carried out in its earlierstages. Some $3,000,000 was spent in the enterprise, and it would undoubtedly have been carried through to success in all its ramifications but for the great achievements

* This seems to be a return to a form which has been several times tried and abandoned in this country, and has very little theoretically to commend it. The early forms of the Immisch motor embodied this principle. See *The Electrician*, October 22, 1886, p. 489.—Ed. *E.*]

Digitized by Google

in submarine telegraphy which gave the United States far better connection with Europe by means of the Atlantic cables. Mr. Sibley remained active in the management of the Western Union Company until 1869, when he resigned office, but he has been engaged in business down to the present time, when, at the age of 81, he died full of honours. It will not be forgotten in the years to come that this shrewd, hard-headed business man was widely philanthropic and public spirited. To Cornell University he gave the Sibley College of Mechanical Arts, on which he spent $150,000; to the University of Rochester, N.Y., he gave the Sibley Hall, on which he spent $120,000; and other benefactions, to the extent of hundreds of thousands of dollars, might be easily recalled.

NOTES FROM VIENNA.

(FROM OUR CORRESPONDENT.)

The Telephone Company of Austria is sparing no pains to develop their business in Austria, and have succeeded in satisfying their subscribers and the Government.

They have increased their subscribers, including private lines to—

565 in Prag.	123 in Pilsen.
453 ,, Trieste.	269 ,, Reichenberg.
250 ,, Lemberg.	145 ,, Bielitz.
276 ,, Graz.	
112 ,, Czernowitz.	Total 2,191.

The wire run has increased to 4,628 kilometres, and the calls in the financial year 1887-1888 to 2,907,583. The service for receiving and transmitting telegrams by telephone has been much appreciated, as the following figures show, viz.: 50,905 transmitted and 23,179 received, total 74,084 during year 1887-88. The Government is also showing great activity in connecting up the various towns and opening exchanges where none had yet been opened.

They have connected Brünn with Vienna, also Baden, Voslau, Wiener-Neustadt, and Reichenau. They propose early in 1889 to run a special line of silicium bronze wire to Prag from Vienna; also to connect Buda Pesth, and perhaps Graz and Trieste. They have opened exchanges in Baden, Voslau, Wiener-Neustadt and Wansdorf, and are arranging the opening of further exchanges in Salzburg, Innsbruck, Karlsbad, Gablonz, and other towns, and have erected about twelve public call rooms in Vienna, where everyone can call up, upon payment of fixed rates per five minutes' conversation, the subscribers of the Vienna Company's exchanges in Vienna and Brünn, also those of the Government exchanges in Baden, Voslau, Wiener-Neustadt and Reichenau. The connection of numerous outlying places to the next telegraph station is proceeding at a rapid rate, thus extending the Austrian telegraph system without great cost.

The new switch-boards made by the Consolidated Construction and Maintenance Company (Limited) are proving very successful, and are largely used in Austria. The Consolidated telephones, as well as the Gower-Bell combination made by this company, have hitherto been unsurpassed for general exchange work, whereas the use of the Bell-Blake and others which have to be constantly regulated is rapidly diminishing. The Vienna Telephone Company is also increasing rapidly. During the last year they have connected up over 300 new subscribers, and are now laying cables for 600 to 700 more, which will cost them nearly £20,000.

Vienna is the only large city which has almost entirely underground cables in use, as Paris can hardly be counted, the cables there being placed in their wonderful system of subways. The Vienna Company had special difficulties to contend with owing to the great difficulty of obtaining way-leaves. Their new multiplex switch-board, made by Mr. Otto Schaffler, of Vienna, is at this moment probably the best in Europe. Although Austria cannot compare with the whole of Germany as regards the total number of subscribers, yet the towns, taken singly, compare very well with German towns of the same size. Germany has about five times as many large towns as Austria, which is a nearly purely agricultural country.

As regards the technical work, Austria is far ahead of Germany. The lines in Austria are all built of silicium bronze wire, in Germany of iron and steel. Austria has newer and better patterns of switch-boards, and far better telephonic apparatus. The German exchanges have lately got to be so bad that the German Goverment has been obliged to ask for a very large sum of money, said to be over £200,000, in order to reconstruct the Berlin and Hamburg exchanges.

All new trunk lines between towns in Austria are being run with silicum bronze wire on separate poles, it having been found that the Van Rysselberghe system does not give good telephonic connection, and spoils the telegraph work. In Germany, Belgium and France, the Van Rysselberghe system is being given up. Much expense would have been spared if Mr. W. H. Preece's advice had at once been taken. Mr. Preece was one of the first who set his face against the Van Rysselberghe's system, though acknowledging the service rendered by Van Rysselbergh to the understanding of various telephonic problems.

It was due to Mr. Preece that no money was wasted in England by trying to utilise this system.

NOTES FROM PARIS.

(FROM OUR OWN CORRESPONDENT.)

An important scheme has been laid before the Municipal Council for the construction of an undergound railway to be worked by electricity from the Bois de Boulogne to the Bois de Vincennes. The tunnel will be lined with an iron tube 5·6m. in diameter, and it is not proposed to open the surface of the ground at more than a few stated points. It is proposed to establish a two minutes' service of trains, and to maintain a maximum speed of 20 kilometres per hour. The estimated cost of the whole is 36 million francs, the construction of the tunnel and permanent way absorbing 22 millions of the total. If the concession is granted before the 1st October, the promoters of the scheme will be ready to guarantee the completion of the section between the Bois de Boulogne and the Place de la Concorde by the 1st July, 1889, as well as to extend a branch line to the Exhibition. The use of accumulators is not contemplated; the current will be taken off a central rail direct from the dynamos. Further technical details are not available at present, but the scheme seems to be a good one, and is in capable hands. The Municipality is merely asked to authorise the works, no financial assistance is requested, and it is not intended to seek a monopoly. But, even upon such terms as these the opponents of reform will certainly discover a thousand objections to the scheme, and for my own part I am not inclined to think hopefully of its prospects. France is sadly behindhand in the matter of electric traction, and I fear is likely to remain so.

Some further details respecting the Paris-Marseilles Telephone line have recently come to hand. The total length of wire out and home is 2,000 kilometres (1,250 miles); the conductor is of silicium bronze 4·5mm. in diameter, having a weight of 146 kilogrammes, and a resistance of 1·08 ohm per kilometre. Fortin-Hermann cables are used wherever it is necessary to run underground. In this cable the conductors are threaded at intervals through small cylinders of paraffined wood, several of these cylinders being then placed in a lead tube. The line has been constructed in lengths of 200 metres, the joints being made by the use of solder and special sleeves on the overhead line. The two wires are run one above another at a distance of ·5m on large double bell-shaped porcelain insulators. During some of the trials a strong north-west gale and the working Hughes' transmitter on adjacent lines gave rise to much rattling in the telephone receiver. Under favourable conditions, however, the transmission is good. The preliminary trials were made with various instruments, but it has been finally decided to use D'Arsonval transmitters and receivers.

NATIONAL TELEPHONE COMPANY.—A dividend for the six months ended June 30 last is announced at the rate of 6 per cent. per annum on the First and Second Preference Shares, and at the rate of 5 per cent. per annum on the Ordinary Shares, as against 4 per cent. for the corresponding period last year, and that of the remaining profits the sum of £2,500 should be added to the reserve fund, and the balance of £3,253 carried forward. The unaccrued revenue carried forward to the credit of the next account amounts to £58,495, as against £49,525 carried forward last year.

CORRESPONDENCE.

THE ARC LIGHT AT EASTBOURNE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The letter published in your columns referring to "Search Lights on Yachts" reminds me that for 48 hours last month there was anchored off Eastbourne a private, large, three-masted screw steam yacht, from which at about ten o'clock each night there was displayed (for amusement, I presume) a most brilliant electric search light, which certainly dispelled any ideas I had formed as to what private enterprise could do in that direction, for I never saw a more brilliant beam nor one more dexterously manipulated in lighting up the desired objects on land or sea. I should think it must have convinced those who had before only seen the flickering arc lights along the parade of that town, that in electric lighting, as in most things, there are varieties of quality and kind. The parade lights always reminded me of some lines in the poem of "The Sacrilegious Gamesters"—

"It shed a restless, waving gleam
Through the gothic window pane;
And now it vanished for a space,
And now it came again."

"He stood, and thought it wondrous strange
That such a scene should be."

It also struck me that there is "in and out running" in other fields than those devoted to horse-racing.

I never saw the incandescent lamps which are used in many of the shops illuminated, but have been informed by those who complain of the unsteadiness of the parade arc lights that they are very steady and highly appreciated. That being so, if the parade lights are on the same circuit, the carbons or the mechanism which is supposed to regulate them must be in fault. Again, I am aware that the source of power is far from the arc lamps, necessitating long leads; but let the cause be what it may it should be remedied as quickly as possible, for as at present arranged it does not in my opinion tend to advance the success of electric lighting.—Yours, &c.,

July 22nd, 1888. WILLOUGHBY SMITH.

EDISON-SWAN *VERSUS* HOLLAND AND OTHERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I beg to inform you that, having been advised that the decision of Mr. Justice Kay is contrary to decisions in the Court of Appeal and House of Lords, the directors have instructed our solicitor to take the necessary steps for appealing against Mr. Justice Kay's judgment.—Yours, &c.,

S. FLOOD PAGE, Secretary.

The Edison and Swan United Electric Light Company,
London, July 19th, 1888.

UNIPOLAR INDUCTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In answer to Mr. N. G. Thompson's letter in your issue of the 13th inst., I would point out that there must necessarily be an increase or decrease in the number of lines of force passing through any area when more lines cross the boundary from outside to inside than from inside to outside, or *vice versâ*. In any case of so-called unipolar induction the number of lines of force passing through the circuit increases continuously at a rate proportional to the angular velocity of rotation. Consider, for example, the simple case of the terminals of a fixed circuit in contact with the central portion of the surface and the extremity of the axis respectively of a cylindrical magnet rotating about its axis. The circuit here increases in length at every revolution by the length of the path described by the centre terminal relatively to the magnet—that is to say, by a length equal to the circumference of a circular section of the magnet. Every line of force proceeding from the magnet will cut the area added to the circuit at each revolution once, and once only; so that the number of lines of force passing through any area bounded by the circuit will be increased at each revolution by the total number proceeding from the magnet.—Yours, &c.,

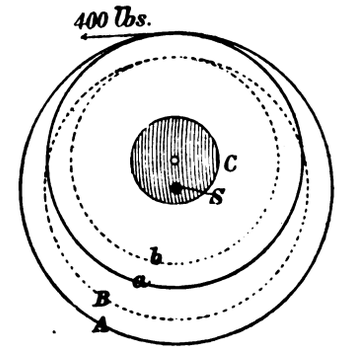
G. W. DE TUNZELMANN.

THE BEAUMONT EPICYCONOIDAL GEAR.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I venture to trouble you with a few remarks on the Beaumont gear illustrated in your issue of the 29th ult., and designed with a view of facilitating the application of electricity to the working of tramways and railways. It is a very ingenious mechanical device, but I do not think it is suitable for the purpose in question.

In the invert wheels A and B and the pinion D carried by the excentric C I recognise all the essential features of an epicyclic train which was designed some time ago by Mr. R. H. Ridout and myself, for pretty much the same purpose as the Beaumont gear is intended for. The Beaumont gear, as you have illustrated and explained it, however, possesses a serious mechanical defect; if A and B are to have a different number of teeth, and still be concentric, and on one axis, they cannot both be made to work truly with the same pinion D; A and B must be wheels of different pitch diameters, and D must consist of two pinions of corresponding diameters, and bolted together so as to turn as one wheel. The combination is then in some respects equivalent to a train of four cog wheels, working together, and possessing a certain velocity ratio; but considered as a means of transmitting power rather than as a means of obtaining a certain change in velocity, the arrangement is by no means a good one. I shall perhaps best make this clear by taking an example.



Let the circle A represent the pitch line of one of the invert wheels, say the wheel driving the axle of the car, and B the pitch line of the controlling wheel; a and b the pitch lines of their corresponding planet wheels, which in the Beaumont gear are represented by the pinion D; the shaded circle C the the excentric carrying them; and the small black circle S the centre of the main driving axle or the armature spindle. As probable dimensions further suppose A = 12 inches radius, B = 11·2 inches, a = 8 inches, and b = 7·2 inches. From these dimensions, and B being fixed, we deduce the velocity ratio to be $\frac{1}{28}$, *i.e.*, B would make one revolution for every 28 revolutions of the armature spindle.

Now, suppose A is also the diameter of the pitch circle of the sprocket wheel driving a chain gearing with another sprocket wheel on the axle of the car, and, say, of a diameter equal to A. To keep a car weighing six tons in motion on an average tramway there will have to be a tension of, say, 400lb. maintained on the chain, and this will also be the pressure between the teeth of the wheels A and a, which gear together. To propel the car at eight miles an hour, A would probably have to make 70 revolutions a minute, and it would probably have about 50 teeth on its circumference. But if A is to make 70 revolutions a minute, the excentric carrying the planet a must make nearly 2,000 revolutions in the same time; and so we shall have nearly 100,000 teeth passing the line of centres every minute. The pressure upon them being 400lb., it would not be a difficult matter to work out the amount of energy absorbed in the friction, given the detail of the shape of the teeth, so that the amount of "slip" could be arrived at.

Digitized by Google

Whatever amount of energy is wasted between this pair of wheels, rather more will be wasted between B and *b*, because with the dimensions assumed the pressure between their teeth will be about 440lb. instead of 400, and they move with practically the same velocity. The energy thus absorbed in friction would be greater than could be afforded from any electrical source of power.

Again, notice that, *neglecting the friction entirely*, the pressure to be kept up by the armature on the centre of the excentric carrying the planet wheels will be about 44lb. when the excentricity is 4in., as assumed above.

Now, compare these figures with what you would get in a simple train of wheels, say a pinion on the armature spindle gearing with a plain spur-wheel of 28 times its diameter, armature running at 2,000 revolutions, pinion 4in. diameter, with 10 teeth. If friction be neglected, the torque of the armature will be the same as before, 44lb. say, and we have $2,000 \times 10 = 20,000$ teeth passing the line of centres, as against nearly 10 times that number in the other case (*i.e.*, 100,000 twice over), and the pressure between them only about 90lb., instead of over 400. From these two sets of figures I think it may be fairly deduced that an enormous waste of power would ensue if the gearing in question were used to transmit anything like the power required on a tramway or railway.

A further very serious waste of power would be found to arise from the use of an excentric to carry the planet wheels *a* and *b*. The axle on which they turn should be as small as is possible consistent with adequate strength. The absolute *friction* between the rubbing surfaces may not be altered by increasing the size of the axle and converting it into an excentric (except in so far as it may be modified by the increased velocity between these surfaces), but the leverage at which this friction acts against the power overcoming it is increased, and so the power absorbed will be increased also.

As objections of another nature with which this gearing would have to contend may be mentioned the probable difficulty of lubricating the invert and planet wheels; of finding space for the apparatus underneath the floor of a tramcar; and, above all, the injurious effect upon it of the violent shaking about which it must get upon a tramway. Experience shows that machinery is far more difficult and expensive to keep in working order on a tramway than it is on a railway; this is partly due to the greater amonnt of dust and dirt to be contended with, and partly to the hard and rigid nature of the permanent way as compared with the permanent way of a railway.—Yours, &c. T. ARNALL.

Birmingham, 17th July, 1888.

PATENT RECORD.

RECENT APPLICATIONS FOR PATENTS.

9,141. C. HUELSER, of the firm of Huelser and Co. London. A new or improved automatic electrifying apparatus (J. Müller, Germany). June 22, 1888.

9,171. W. E. LANGDON. Derby. Improvements in electric lighting as applied to railway trains. June 23, 1888.

9,206. C. LÜTKE and P. GEORGE. London. Improvements in galvanic elements or batteries. June 23, 1888.

9,224. G. HOOKHAM, Birmingham, and R. H. HOUSMAN, Bromsgrove. Improvements in the distribution of electric currents from central stations. June 25, 1888.

9,254. B. M. DRAKE, J. M. GORHAM, E. MANVILLE, and W. L. MADGEN. London. Controlling devices operated by means of the thermic effects of electric currents. June 25, 1888.

LEGAL INTELLIGENCE.

The Gaulard and Gibbs Patent.

In the Royal Courts of Justice (Chancery Division), before Mr. Justice Kekewich, the above case was mentioned on Tuesday morning, on an application to stay proceedings, judgment having been given on a former occasion against Messrs. Gaulard and Gibbs.

Mr. ASTON, Q.C. (who appeared for Messrs. Gaulard and Gibbs), said he was instructed to make a formal application to his lordship that the proceedings in this case might be stayed. He ought to say that upon his lordship's judgment, in his opinion, the plaintiff could go to the Registrar's Office and apply to have Gaulard and Gibbs's patent struck off the register. Of course, that would be a proceeding which might be very inconvenient to the parties. He will undertake to lodge the appeal at once.

Mr. JUSTICE KEKEWICH: Well, it cannot be heard under six months.

Mr. ASTON: I imagine not.

Mr. JUSTICE KEKEWICH: It does not seem to me to be a generous offer.

Mr. ASTON: I think that your lordship will remember the circumstances of the case. Our relations with the Grosvenor Gallery, who are practically the persons interested in this case, are of a very amicable character. I think that the proceedings should be stayed for a while.

Mr. Justice KEKEWICH: Can you suggest, Mr. Moulton, what is fair to both parties?

Mr. MOULTON: I certainly wish to give it as my opinion that your lordship's judgment is the revocation of the patent.

Digitized by Google

Mr. Justice KEKEWICH: That I do not intend to go into. It is a new question which I am not called upon to decide. If I am bound to do so I shall not shirk it more than any other question.

Mr. MOULTON: Quite so. What I feel is that my learned friend is asking an indulgence which I cannot say has any very prejudicial effect upon my client, and at the same time I think that it ought to be granted, and that we, having obtained your lordship's judgment, should undertake not to take any actual steps with regard to doing anything at the Patent Office until the appeal is heard, provided that the appeal is lodged at once; but it should be on terms.

Mr. Justice KEKEWICH: They are cross undertakings. You are to appeal, and Mr. Moulton undertakes to do nothing.

The Simplex Electric Light and Plant Company (Limited) v. Cooper and Craig.

At the Manchester Assizes on Monday last this case came on for hearing. Mr. Bigham, Q.C., and Mr. Hopkinson were counsel for the plaintiff company, and the defendants were represented by Mr. Gully, Q.C., M.P., Mr. Yates, and Mr. Brierly. The action was brought, Mr. Bigham said, to recover the price of installing the electric light at the colliery of the defendants, in Staffordshire, and also to recover several items for goods supplied and work done. The defence, briefly stated, was that the plaintiffs did not do their work to the satisfaction of the defendants. After opening the case Mr. Bigham suggested that the better course would be to refer the matters in dispute to a practical electrical engineer.

The JUDGE said he did not like to shrink from any duty that was cast upon him, but in any event a considerable portion of the case must be referred, because, to some extent, the case was one of accounts, and under all the circumstances he thought the parties would be more likely to arrive at a satisfactory settlement by referring the disputed points.

After counsel and clients had consulted together,

Mr. GULLY announced that it had been decided to refer the case to a gentleman to be agreed upon between the parties. If the parties could not agree upon the referee, application would be made to his lordship to nominate a gentleman.

COMPANIES' MEETINGS & REPORTS.

Anglo-American Telegraph Company (Limited).

The ordinary general half-yearly meeting of the proprietors of this Company was held yesterday, at Winchester House, 50, Old Broad-street, the Most Hon. the Marquis of Tweeddale presiding.

The SECRETARY (Mr. T. H. Wells) read the notice convening the meeting, and the minutes of the last ordinary meeting, held on February 3rd, which were signed by the Chairman as correctly entered.

The Directors' report and statement of accounts were taken as read.

The CHAIRMAN: Gentlemen, it is now my duty to ask you to adopt the report and accounts, but before doing so I must be allowed to express my great regret, which I am sure will be shared by everyone present, that our worthy Chairman is unable to preside on this occasion. The indisposition which has prevented him from coming here is not of a very serious character, but his medical attendant insists on his remaining quiet at home. I am sure you will all join me in the hope that he will soon be restored to his usual health. Gentlemen, the report and accounts which have been in your hands for some days, which no doubt have been perused by you with the care and interest which they deserve, are so full and give you such ample information as to the proceedings of the past six months, that it will be wholly unnecessary for me to occupy your time at great length. At the same time, with your permission, I shall trouble you with a few observations on the more salient points. Turning, in the first instance, to the accounts, you will observe, no doubt with satisfaction, that the working expenses show a reduction of a little over £1,100. The repairs of cables are considerably less than they were at this time last year, the amount being £5,981, as against £9,858. This is accounted for by the fact that the expenses of the ship "Minia" have been charged to renewal fund, inasmuch as the ship was employed in renewing a very considerable portion of cable which had been destroyed. That item amounts to £15,485, which has been expended during the six months under notice. The repair was a very costly one, and was in connection with the Brest-St. Pierre cable, which was broken in three different places. One break was at a place no less than 2,000 fathoms in depth; the second was at 400 fathoms; and the third at 900 fathoms. The one at the depth of 2,000 fathoms has been successfully repaired, and the other at 400 fathoms has also been repaired, and the third, which is at the moderate depth of 900 fathoms, is in course of being repaired, and we have every reason to believe that news will reach us in a few days of the successful repair of that cable also; in fact, as far as we can make out, the delay is entirely due to a very thick fog which has been prevailing in the neighbourhood of Newfoundland. Those repairs have been costly, as might be expected; but fortunately we have a very valuable, I may say indispensable, fund to which we have been able to charge the cost of those repairs so far as we know the amount. That leads me to draw your attention to the fact that the renewal fund now amounts to the very handsome sum of £909,694, but in reality it is worth a great deal more. The securities in which your fund has been invested would yield now something like £50,000 over and above their cost price. Gentlemen, so far I think it must be admitted that the features of the report which I have dwelt upon are satisfactory. What is not quite so satisfactory is the reduction of our receipts, which, as the report informs you, amount to the sum of £19,635. The cause of this is explained in the report, and is due to the fact that the Commercial Cable Company, which charged a 1s. rate while we were charging the 6d. rate, altered it to 6d., thereby obtaining a considerable addition of traffic, or, rather, subtracting traffic from us which we had been enjoying before. The only observation that that seems to call for is that we must deem ourselves fortunate that they did not make the change at an earlier date. That brings me to the very important question of the tariff. You are aware that the 6d. tariff was adopted in the hope and belief that it would prove a remunerative tariff. It was hoped that so low a rate as 6d. would, in the course of time, augment the messages to such an extent that the 6d. tariff would become the tariff of the future. Well, gentlemen, the experiment has now extended over two years, and we, in common with all companies dealing with telegraph traffic across the Atlantic, have come unanimously to the conclusion that the 6d. tariff not only is not a remunerative tariff, but will not be so within any reasonable time; that I think we are all agreed upon. It is very much to be regretted that this is the case. For the first year the results were very promising. The increase amounted to something like 140 per cent., and if that increase had gone on at the same figure we probably should not have had to change the rate now. But, as the report informs you, the increase ceased about a year ago, and therefore we know pretty well the effect of the 6d. tariff upon our finances. The companies having come unanimously, I may say, to the conclusion that the 6d. tariff is not a paying one, nor is likely to be within any reasonable period, negotiations have been set on foot with the view of raising the rate. Those negotiations are proceeding at this moment, and I think I may say that there is a reasonable prospect of their being concluded in a satisfactory manner within a very short time. The negotiations are on the basis of a 1s. tariff. Now, gentlemen, if, as we believe, a 1s. tariff will not lead to any serious reduction in the number of messages, the revenue will benefit very considerably, and I need hardly add that we hope for a better dividend than it is my duty to recommend to you on this occasion. Most of you are aware with reference to our law suit with the French Company that it has been gained by us, and very large damages accrue in consequence of the decision in favour of this Company, and what I want to mention is that no credit has been taken for any portion of the damages which have been awarded to us. Therefore, if at any time any portion of these damages come into the exchequer of the Company so much the better will it be for the proprietors. I may also add with reference to the French Company that they have made claims which have delayed the negotiations somewhat—claims which we could not admit—and that is the reason that I am not able to report the conclusion of the negotiations to which I have referred. Gentlemen, with these observations I beg to move

"That the report of the Directors, with the accompanying statement of accounts to the 30th June, 1888, submitted to this meeting, be and the same are hereby received and adopted."

Sir JAMES ANDERSON seconded the motion.

Mr. SMITH said that he quite agreed with the noble Chairman's remarks that there had been a decrease in working expenses, but he thought that his lordship had made a mistake in the comparison. He (the speaker) made the saving of the present half year, compared with the last half year, £4,000.

The CHAIRMAN: £1,100.

Mr. SMITH (continuing) thought that very great credit was due to the Directors for the very able manner in which they had invested the proprietors' money. There was not the least doubt that their investments had increased in value by something like 13 or 14 per cent. Certainly the market value of their renewal fund had increased over 10 per cent., and seeing that the whole of the repairs would soon be completed, he thought the shareholders would agree with him that the time had now arrived for carrying out the understanding that they came to some time ago with their Directors, that the interest of the renewal should be used as revenue. He thought the whole of the interest of that fund should be now added to revenue. If they adopted that course it would increase in these hard times the dividend upon the Ordinary Stock by half per cent. He was sure that the shareholders had shown the greatest patience during the last two or three years by the very small amount of dividend which they had been satisfied with. He would move

"That the whole of the interest from the invested renewal fund accruing from 1st July, 1888, be carried to revenue account."

He did not think that anyone could object to that, and that, under present circumstances, it was a very reasonable resolution. Perhaps he might ask whether, in making the agreement with the other companies, it was merely a tentative agreement, and whether the Company would be bound by it for any fixed time. He supposed they would have the power, if the 1s. tariff did not work out to the satisfaction of themselves and the other companies, to advance the rate.

The CHAIRMAN desired to point out that the amendment was not an amendment on the report, because it dealt with the future. He would therefore suggest that the discussion on the report should be taken now, and Mr. Smith's motion afterwards.

Mr. GUESDON thought that the question of the agreement with the other companies should be left to the discretion of the Directors, who were much better qualified by their position than the shareholders to decide upon the conditions to be made with the other companies. He objected to any interference with the reserve fund. He believed in a strong reserve, and the Directors dealt with theirs in a perfectly sound and intelligible manner as business men. The amount of expenses to that account was £15,485, and it was credited with interest to the amount of £15,938, so that the one about balanced the other. He believed that was a sound way of dealing with it, and he would move as an amendment that the reserve

Digitized by Google

fund be left entirely under the control of the Directors at present. Their first object was to establish the Company, and put it in such a position as to the reserve fund as would make it a terror to those men who would endeavour to injure it for their own selfish purposes. He believed a reserve fund was to an institution of this kind what a standing army was to a country. They could not afford to neglect their defences, and the best defence against attack was a fine reserve fund such as they had built up.

The CHAIRMAN repeated his request that the matter should be left until the report was passed.

Mr. HUMPHRIES objected to the form in which the accounts were made up. He protested against the repairs of the cable being put to the renewal fund, and not to the reserve account, making two accounts instead of one. If the whole of the expenses were put to the revenue account, it would increase the expenditure from £34,000 to £56,000.

Mr. JACKSON thought that paragraph 8 in the report wanted a little explanation, which, perhaps, his lordship would give in a definite form: "The attention of the public has been frequently drawn through the press to the large amount of the Company's capital, and this is alleged to be the sole reason why low rates cannot be made profitable upon the cables of this Company." He thought a great deal of emphasis was put upon the press as regarded the consideration of that question, and he wished to say a few words, if possible, to traverse that allegation, which he thought was totally unjustifiable. He contended that that seductive recommendation, that they should write down their capital, should be met as it was by Lord Monck eighteen months ago at their meeting in February, 1887. His lordship then laid it down clearly that it was no advantage to this Company to write down the capital to a nominal amount, and pay on £50 of their capital 5 per cent., which would be simply equivalent to 2½ per cent., which they might hope to get if the proposed alteration of tariff to a moderate amount was carried into effect. He thought the Directors ought to set their faces against creating a fictitious appearance of prosperity of that character. His experience of companies that had written down their capital was that they had done it because of their impecuniosity, and that they steadily declined in value. It was unsound finance. It was urged, why should they go on paying a dividend on a capital that did not exist? He contended that it did exist, and could easily be shown. It was just as reasonable for the press to say of railways that they should value their plant, their engine sheds, stations, and their land at its present depreciation, and then be content with a moderate dividend on that valuation. It was a monstrous absurdity. He wished to call the attention of the shareholders, and particularly of the press, to this extraordinary fact as regarded the Anglo-American Company, that for no less than 15 years not a pound of additional capital had been created. The capital account was closed in 1873, as could be learned from all their reports, and not a pound had been added to it; and therefore the proposition was a very insidious one. They could not allege that there had been extravagance on the Board. There had been want of care, perhaps, on the Board, and there had been no want of self-denial among the shareholders. What had been the result? For the last 10 years their dividend had not averaged 3 per cent. It was at the rate of 5s. 2d. for the last half-year and 6s. 3d. before, which was a little less than 11s. 6d. per annum for the important services they had rendered to the commercial and mercantile world. He maintained that they stood in a position unexampled, and that the shareholders would be most unwise and egregiously oblivious of the long sacrifice they had made to build up their renewal fund, out of which they had paid for their renewals and repairs without adding to their capital a single pound on which any dividend was to be paid, if they listened to such a proposition. He was grieved and surprised to find such a paragraph in the report, which he thought greatly affected their future. It was contended that they had "watered" their capital. He admitted that the original 1866 capital of the Anglo-American Company was doubled because it was an unexpected and wonderful success, two cables having been supposed to be utterly lost previously in the sea. What were the concessions obtained? First of all the shortest route in existence, by which a saving of 900 miles of ocean in the making of the cable was effected, and the land lines in Newfoundland were obtained, and the result was that the shareholders who, like himself, were in the 1865 cable company, that existed for 18 months, got for every £100 stock, on which he had paid a considerable premium, £42 in the new Company. Their 1874 cable had cost £475,000, and was paid out of renewal fund and out of reveuue. In 1880 another cable was laid down out of their hard savings and diminished dividends, at a cost of £330,000. He thought it hardly fair that the Board did not impress these facts on the outside world, the press particularly, who could not be supposed to be intimately acquainted with the history of the Company, extending over so many years. He did hope that they would stand by their capital. As to dividend, none of them expected, or ought to desire, anything but a moderate dividend from an international service, and under the circumstances they were entitled to it. He did not believe the press would urge the extension of great undertakings of the kind at the expense of the shareholders. He must demur to the statement of the Chairman that the sixpenny rate was ever expected to pay. He for one could never have believed it. As to the shilling rate, he was quite satisfied that no reasonable merchant, or any member of the Stock Exchange, would say that it was extravagant.

Mr. SEELY was surprised that the Board had been two years in finding out that the sixpenny rate could not pay. The Directors admitted, too, in the report that the rebound in the number of messages took place about twelve months back, and therefore it still was his conviction that it was really a fighting rate. The last speaker hoped that they were going back to a position where they might get a fair remuneration for the capital employed. The question was, What was a fair remuneration? Was 3 per cent. a fair return? If they went back before the war of rates they had not received more than 3 per cent. dividend for two or three years, and their rate was 2s. a word. It was not the first time that an unfortunate war of rates was tried. It was the second time, and the result had not been advantageous. They were only a commercial Company carrying messages, just in the same way as any form of trade might be carried on, and if other traders would start in opposition to them the best thing they could do was to arrange a tariff and work in harmony with them. He asked whether it was possible that the 1s. tariff could pay them 3 per cent.? They were working for two or three years at 2s., and they never exceeded 3 per cent even then. He therefore hoped that the Board, before they made any arrangements with other companies, would very seriously consider that question, and go on striving, with their miserable dividend, to force others to the same view as themselves upon the subject of the tariff.

The CHAIRMAN, in reply to Mr. Smith, said that he thought the terms of the agreement with the other companies might be safely left in the hands of those who were negotiating it. He was glad to hear such eloquent support of their policy with regard to the renewal fund from one so competent to speak on the subject as Mr. Guesdon. He must point out to the last speaker that there were many people of great knowledge of the subject who fully believed that within a reasonable time the sixpenny tariff would pay, on the same principle that lower rates had led to large increases of business in railway, omnibus, and other companies, not to speak of the great success which attended the Post Office reductions of rates. As he said in his opening speech, during the first year the augmentation of business was most encouraging, but it seemed a year ago to suddenly stop and go back. One advantage they gained by the low tariff was that they kept off competition, for, as would be remembered, one or two very serious attempts were made to obtain money from the public to lay cables across the Atlantic, and he was not at all sure if they were to raise the tariff beyond 1s. whether some such schemes might not crop up in the future, when they might be in a worse plight than they were in now. Mr. Jackson referred to the question of writing down the capital, but he (the speaker) could only say in reply to that, that the Directors had no intention of proposing anything of the sort, and therefore it was unnecessary for him to deal with the subject.

He then put the motion to the meeting and declared it carried unanimously.

Continuing, he said he wished to make one or two remarks upon the motion of which Mr. Smith had given notice. He was not sure it was a proper motion. He had no desire to do anything in the nature of stifling discussion, especially on so important and interesting a matter as the application of the interest on renewal fund. They must all know that the Board had every desire to give the shareholders the benefit of everything they thought could be given consistently with the interests of the Company. There was another objection to it, he would venture to mention, and it was that no notice of the proposal had reached the distant shareholders, and it was therefore impossible for them to know what might be the opinion of those shareholders on the matter. He had, as he said, no desire to stifle discussion, and if Mr. Smith would not object to put his proposal in a somewhat different form, he would then be very glad to take the sense of the meeting upon it. The suggestion that he would make would be that the motion should read

"*That in the opinion of the stockholders present at this meeting it is desirable that from 1st July, 1888, the whole of the interest arising from the investments of renewal fund be carried to revenue account.*"

Mr. SMITH accepted this, and said he saw no objection to put his motion in the form of a recommendation, repeating, however, his opinion that the time had now come when the interest on the renewal fund should be distributed as dividend.

Mr. JOHN NEWTON seconded the motion.

Mr. GUESDON again protested against any interference with the renewal fund. He did not pretend to be a large shareholder in the Company, but he held a sufficient stake in it to warrant him in expressing an opinion upon the question. He did not hold his shares for the value they might represent on the Stock Exchange, he held them as a source of revenue, and he wanted to see the Company occupy a permanent position of prosperity. He moved as an amendment

"*That the disposal of the interest of the investment of the renewal fund be left to the discretion of the Directors.*"

A SHAREHOLDER seconded the amendment.

Mr. JACKSON said he saw no difference between the motion and the amendment, Mr. Smith's motion being simply a recommendation to the Directors to consider the advisability, in the interests of the shareholders who were receiving no dividend from the earnings of the Company, of distributing the interest on the renewal fund. They did not want to force the hands of the Directors, but they said they were fairly entitled to the interest on that fund.

After a few more remarks from Mr. SEELY,

The CHAIRMAN said he wished to draw their attention to the agreement that was entered into by the shareholders with the Directors, Mr. Smith himself representing the shareholders. The agreement was that the Directors would stop further contributions to the renewal fund when that fund had amounted to £1,000 000. After that date the interest of the fund alone would be added to the principal. Therefore Mr. Smith's resolution was somewhat at variance with the agreement, and he must say that the Board were of opinion that a million was not too much for the renewal fund, and therefore Mr. Smith could not expect any support from the Directors, although it was only fair that it should be put to the meeting.

Mr. SMITH said the circumstances were not identical with those when the agreement was entered into.

The CHAIRMAN then put the amendment to the meeting, which he declared carried by a show of hands.

A vote of thanks was afterwards passed to the Chairman and Directors, and the proceedings terminated.

The Direct United States Cable Company.

The twenty-second ordinary general meeting of this Company was held at Winchester House, 50, Old Broad-street, on July 20th, under the presidency of Sir John Pender, K.C.M.G.

The ACTING SECRETARY (Mr. T. Finnis) read the notice convening the meeting, and the minutes of the twenty-first ordinary general meeting, held on January 20th, which were signed by the Chairman as correctly entered. The report of the Directors was taken as read.

The CHAIRMAN then said: Gentlemen, before I move the resolution for its adoption I shall make, as usual, a few remarks upon the report, and also upon the present position of the Company. The revenue for the half-year (after deducting outpayments), and including income-tax refunded, amounted to £17,508, and the working and other expenses, including income tax, but exclusive of cost of repairs, absorb £15,277, leaving a balance of £2,231 as the net profit of the half year, making, with £9,911 (composed of £6,899 interest and profit, and £3,012 only of principal) transferred from the reserve fund account, a total of £12,142, which has been appropriated to the payment of the following dividends:—Interim dividend of 2s. per share for quarter ended 31st December, 1887, £6,071; interim dividend of 2s. per share for quarter ended 31st March last, £6,071—total, £12,142. A final payment of 2s. per share for the quarter ended 30th June is now proposed, making, with the three interim dividends already paid, a total of two per cent. for the financial year. The revenue, owing to the low rates current, shows a reduction of £6,C64 as compared with the corresponding period of last year. The expenses in London show a reduction of £583 in salaries, and an increase of £77 in stationery and printing, the remaining items being about the same as in last year. The expenses at stations show an increase of £60 in house allowances, £106 in maintenance, £45 in rent, £109 in travelling, and £59 in repairs, principally owing to outlay at Halifax station. The other items continue practically unaltered. In the further expenses directors' fees are reduced by £157, and use of patents by £126, and the half-year's income-tax is less by £286 than in the corresponding period. On the whole the expenses and other payments exhibit a reduction of £628. The cost of the current repairs amounted to £25,222 to 30th June. This sum is at present standing in the balance-sheet, but will be dealt with later on, together with the cost of completing the repairs. The investments continue worth much more than they cost the Company. These are figures which give you a thorough knowledge of the way your affairs have been dealt with during the past six months. When I last had the pleasure of addressing you I went fully into the details of the negotiations that were then going on with regard to raising the rates. As you are aware we have given the 6d. rate a thoroughly fair trial. We have been working at it for two years. Some of our friends were sanguine enough at one time, when they saw the traffic going up almost by leaps and bounds, to feel that the 6d. tariff might eventually be a tariff sufficient to enable us to pay a fair dividend. I confess I never believed a 6d. tariff would give us anything like a dividend. The result has been that for two years we have been, as you see we are to-day, paying a dividend, a portion of which comes from the actual working of our system, and the remainder principally from the interest on our invested reserve. Consequently we have been up to to-day in a position which I think is not creditable to business men. I expressed a very strong opinion when I last addressed you, and I said I thought the time would come when a conference ought to be held at which we should take into consideration the question of advancing the rate. At that time there were very considerable difficulties, and I saw clearly that to press anything like a conference wou'd do more harm than good. At the same time I saw that we had made an impression, that we had sown seed that was likely to fructify, and which would in time show good results. I am pleased to tell you to-day that those negotiations which have been going on more or less ever since our last general meeting have culminated now in the Anglo-American Company, the Western Union Company, the Mackay-Bennett Company, and the Direct Company seeing the folly of going on any longer at a 6d. rate. There is one exception to this, and that exception, I expect, will be dealt with on Monday—I refer to the French Company. About two years ago that company—it is probably a little less than two years ago—were most anxious that we should go back to the 1s. 8d. rate. There were very good reasons then why that could not be done. We had entered upon a policy of low rates, and we had to show how far the different parties were satisfied with the result of that. We have proved by going down to 6d. what a 6d. tariff can do, and that tariff is unsatisfactory. Representatives of the French Company, I expect, will be here on Monday, and I see no reason why they should not agree with us; in fact, I think I might almost assume that they will agree with us in putting up the rate, and, if they do the result will be that on the 15th August we shall be working at 1s. instead of 6d. Now, if the whole of the traffic at present carried at 6d. be maintained under the 1s. rate, the total receipts would be much about what they were when the rate was 2s., when we were paying you fair and respectable dividends, but the earnings of the pool would of course now be lessened by the proportion carried by the Commercial Company. If the public do not give us the same amount of support at 1s. as they do now at 6d., it will be for our consideration a year hence—as we shall give the 1s. rate a year's trial—whether we should not readjust the rate again. I hold that a concern is not managed fairly to the shareholders or to the public if it is worked under prime cost. We shall try during the year to do the best we can to develop the traffic and to serve our customers, and if we can establish a 1s. rate as a permanent rate we shall have done a good service to the shareholders and a very beneficial act for the telegraphing public. I have told you so far what is now before you, and I think you may look forward with perfect confidence to having the 1s. rate established, and that at a very early period indeed. Now, in regard to that part of the business—which I call a very important part, as it affects our dividend—I have given you all the information I am in possession of. I have kept nothing back, and I think the different parties interested are all entering into an honourable obligation, that there are to be no rebates and that the agreement is to be fairly and honourably conducted. If we find there is any departure from that I shall be the first to protest against it. I think, however, this arrangement which is now being entered into by the different telegraph companies will be carried on in a straightforward business way; and if it is carried on in that spirit I am sure that we shall benefit by it. Now, gentlemen, I had hoped to-day to give you a second budget of good news. I had hoped to be able to tell you that our cable was repaired, and in thorough working order, and I am enabled to tell you that we have taken out one of the most important faults in the cable. We have lifted the cable from over two thousand fathoms of water—two thousand two hundred—taken out the fault, and made the repair. That is a very great fact, and a very great feature in submarine telegraphy. To lift from 2,200 fathoms a cable that has been lying in the sea for nearly fourteen years is no small point at the present moment. It is one which scientific men must recognise as one of the great features of the times. It is one of those questions which those who are interested in submarine telegraphy must recognise as giving stability and character to their property, which, probably, some have not felt up to this time. To be able to repair a cable after fourteen years' submersion, and lift it from 2,200 fathoms of water, shows really that we have got such a knowledge of our business as will enable us to say with confidence that we possess something like a permanent property. The fact that you have not heard to-day of the completion of the repair is attributable, no doubt, to that which every one of us is complaining of at the present moment, that is the weather. I believe they are having very stormy weather in the Atlantic, and, as you know, it is impossible to repair a cable in a storm. We have to wait for calm quiet days, and in those calm quiet days we are able to carry on this important work. We believe that the ship is at the present moment within 600 miles of the Irish coast, in which position she has lifted and buoyed one end of the cable, and is only waiting for a spell of good weather which will enable us, we believe, to thoroughly repair the cable. The amount of cable put in will almost give us a new departure. We shall then be able to work our cable, and not only contribute our share to the pool, but we shall also be able to work our duplex system, which we have not been able to do on account of these faults. Therefore we shall take the position that we always desired to take in the pool—to do our full share, if not more than our proportion, of the work of Atlantic telegraphy. Now, I think I have pretty well told you the whole story of the Direct United States Cable in the last six months. I have shown you that we have done a bad business, which I am free to admit; but I have shown you that we have done a good business at the same time, in beginning—and I hope in quickening, to some degree—the conclusion of the 6d. rate. We have proved that that rate will never pay. It is impossible it can ever pay. We are therefore, I say, now taking a new departure, and that departure is likely to ensure us receiving better dividends than we have had in the past two years. With these remarks I move:—

"*That the report of the Directors, dated 6th July, 1888, together with the statement of accounts to 30th June, 1888, annexed thereto, be and the same are hereby received and adopted; and that a final dividend be now declared of 2s. per share, free of income-tax, making, with the interim dividends already paid, a total dividend of 2 per cent. for the year ended 30th June, 1888.*"

Mr. WM. FORD seconded the motion.

The CHAIRMAN having expressed his readiness to answer any questions,

Mr. GUESDON asked in regard to the negotiations with the cable companies, with the view of readjusting the rates, whether the arrangement come to was under a "pool," or whether the Commercial Company was to be in any distinct position from the other companies with respect to the working and profits of the cable. He was glad to hear the Chairman say that he hoped the 1s. rate would pay. Many years ago the Chairman expressed a strong conviction that a 1s. rate would not pay. He himself felt that a low rate would mean a large extension, and while the 6d. rate was insufficient to realise fair profits for the shareholders, it had developed one great fact—that low prices had increased to a larger extent than he had thought possible the use of the wires. He hoped, unless the traffic fell off very much, that they would be able to maintain a 1s. rate between the two great English speaking races. He was anxious to see submarine telegraph business carried on at a price favourable to all parties. He was not one who looked for 10 per cent. dividends, as those days were gone. He inquired why the cost of the patents had been less, and said he assumed, although it had not been stated, that the cost of the repairs to the cable would be charged to the reserve fund.

The CHAIRMAN, in reply, said that they had no "pooling" arrangement in regard to the raising of the rate. The old pool would continue, but the Mackay-Bennett Company would simply come into the arrangement to raise the rate, and they were particularly anxious that the rate should be raised. They, in fact, always desired that the rate should have been increased to 1s. 8d., not to 1s. It was the English companies who had fought for the 1s. rate, and they believed that if they got the same amount of traffic at 1s. which they had been getting at 6d., they would be brought into the position of paying fair and moderate dividends. He repeated what he had said before, that if they were to work at the 1s. rate with only the same amount of traffic which they had when they charged 2s. it would not pay, and he had not changed his opinion in that respect in any way. With regard to the less amount which had been paid for the use of patents, that was owing to their

Digitized by Google

not paying for their patent rights during the interruption of the cable. They had contracted with the Telegraph Construction Company to carry out the repairs to the cable. He had satisfied himself by inquiring elsewhere that that company could do the work on better terms, and he had been fortified in that view by the opinion of their special advisers Messrs. Clark and Ford. They had to furnish 300 miles of cable for the repair, and that was an important work. Taking the matter all round—the cable, the ship, and the experience—they found that their interests would best be served by placing the contract in the hands of the Telegraph Construction Company. They could not specify that the work was to be done in a certain time; but they were paying for the cable, and they would pay so much a day for the ship; and it was therefore so much to the interest of the Telegraph Construction Company to show how quickly, cheaply, and efficiently they could effect the repair, for in that manner they would increase the high reputation which they already held. With regard to the reserve fund Mr. Guesdon was quite right. The cost of the repairs must be taken from that fund, on which they had had to draw to a small extent in order that the shareholders might have some return. They would like, however, to be able to add a little to that fund, so as to bring it up to its former amount, as he believed that the reserve fund was the backbone of a concern like theirs.

In reply to Mr. Jackson, the CHAIRMAN added that possibly the French Company, in order to acquiesce in the proposal for increasing the rate, might require a *quid pro quo*. As they were aware, a question was pending between them at the present moment. Probably the French Company had found out that they had made a mistake in raising that question; but that point was outside the question of raising the tariff. If the French Company did not agree to that they would pursue a policy different from what they had lately pursued, and a policy so inimical to the interest of the other companies that he believed they would be strong enough to carry their point.

Mr. JACKSON said he had been glad to hear of the proposal to increase the tariff. He thought the 6d. rate had lasted too long already.

The CHAIRMAN: Certainly.

Mr. JACKSON (continuing) drew attention to the large amount that would have to be paid for the repairs, an amount which he said would come to something like two years' dividends; and he thought that should serve as a warning to any future competing companies, letting them see, as it did, what risks they ran, and what their prospects were of profits. He thought their business would depend essentially on the energy with which it was conducted.

Mr. FRY asked whether the shareholders were to understand that the French Company were to come back into the pool, for that Company had treated them most unfairly, and in a most unbusinesslike manner.

The CHAIRMAN said that that was a matter that was in the hands of the lawyers at the present time. What would be decided in the matter he was not prepared to say, but he agreed that the French Company had acted very unfairly in leaving the pool; and their position was much weaker now than it would have been had they kept to the arrangement into which they entered. In further reply to Mr. John Newton, the Chairman said that the pooling question was not involved at all in the arrangement for raising the tariff to 1s.

Mr. NEWTON expressed great satisfaction at the Chairman's intimation as to lifting the cable from a depth of over two miles and successfully repairing it. He considered that that added to the stability of their position, and justified the view which he expressed some years ago that the Chairman was not entitled to state that the life of a cable was only 10 years. He (Mr. Newton) pointed out at the time that there was not sufficient experience to justify such a view, and that, on the contrary, the cable between England and France had been down for 21 years.

The CHAIRMAN said that there was a time when sound scientific men believed that it was impossible to lay a cable in the Atlantic. Other scientific men said that if a cable were laid it could never be picked up again. This view had been proved to be wrong, as the result of experience. He himself was certainly open to conviction, and when he saw a thing done he was only too glad, and did not in any way dislike it because it happened to disprove an opinion he had formerly expressed. Progress was being made and he accepted good things as they occurred.

Mr. WEATHERLEY thought the Board should forego some of their remuneration, and he maintained that the fact that the dividend was only 2 per cent., and that was being paid out of the reserve fund, showed that some alteration was necessary in the administration of their affairs.

The CHAIRMAN said that the Company was managed with complete efficiency, and Mr. Weatherley, in referring to this matter, had forgotten the fact that it had been the wish of the shareholders that they should adopt the 6d. rate and that something should be taken from the reserve fund account to supplement their dividend. In fact, everything had been done in accordance with the wishes of the shareholders.

Mr. HOOPER wished to know whether the interruption to the cable was attributable to any specific cause that was not likely to recur, or whether it was owing to decadence which was likely to cause the expenditure which they were now incurring to come upon them again. He also desired to know how much less they had received from the pool, owing to their inability to carry messages in the past half year.

Mr. UNDERDOWN observed that they had not lost anything.

The CHAIRMAN said that their arrangement in connection with the pool enabled them to go on for some time until they had effected their repair, receiving the same proportion of the revenue. They were, however, bound by their agreement to make their repair as speedily as possible. They made an important change in the position of the cable last year, removing it from a place called Brown's Bank, which was such an insecure place that they were frequently put to expense in repairs, and they had now placed the cable in a position of much greater security, and relieved themselves of the outlay which they had frequently been subjected to previously.

The motion was then put to the meeting and carried unanimously.

The CHAIRMAN then proposed the re-election of Mr. William Ford as a Director.

Mr. E. M. UNDERDOWN, Q.C., seconded the motion, which after some discussion was carried unanimously.

The CHAIRMAN then proposed the re-election of Mr. C. J. Günther as a Director.

Admiral R. C. MAYNE, C.B., M.P., seconded the motion, which was carried unanimously,

Mr. John G. Griffiths and Mr. John Sawyer were afterwards re-elected auditors.

Mr. NEWTON proposed a vote of thanks to the Chairman, who, he said, had answered all the questions which had been put to him in a straightforward manner. They obtained from Sir John Pender information which they never received from any other Chairman.

Mr. JACKSON seconded the motion, which was carried unanimously.

The CHAIRMAN having acknowledged the vote,

The proceedings then terminated.

Eastern Telegraph Company (Limited).

The thirty-second half-yearly ordinary general meeting of this Company was held on Thursday, the 19th July, 1888, at Winchester House, 50, Old Broad-street, Sir John Pender, K.C.M.G., in the chair.

The SECRETARY read the notice convening the meeting, and the minutes of the thirty-first half-yearly ordinary general meeting of the shareholders, held on the 19th January, 1888, which were signed by the Chairman; and the report having been, at the request of the meeting, taken as read,

The CHAIRMAN said: Gentlemen, before I ask you to approve of the resolution which I shall submit to you to-day I shall make, as usual, some remarks upon the report, so that we may give you the fullest possible information as to the working of this system during the last six months. Our revenue for the past half year amounted to £359,706, as against £331,862 in the same period of 1887, or an increase of £27,844. Included in these figures is an amount of £31,200 dividend on our investment in the Eastern and South African Telegraph Company, as compared with £23,400 last year, an increase of £7,800. As stated in the report, nearly all the shares in the Eastern and South African Telegraph Company belong to the Eastern Company. It is, therefore, most satisfactory that we should receive a dividend of 2 per cent. more than last year. The Black Sea Telegraph Company, owing to an interruption of the cable, shows a falling off of £1,300, this company having declared a smaller interim dividend than usual; but we are not without hope that the final dividend for the year will make up in some measure the lower interim distribution. Our investments in Direct Spanish Telegraph Company's Ordinary Shares give a return of £676, as against *nil* in the corresponding six months. The Direct Spanish Company, in which this Company has a controlling influence, has now turned the corner, and will, we expect, in future give a good dividend to its shareholders. The total working expenses amounted to £87,134, against £83,035, or an increase of £4,099. This is principally caused by the increase of work. The amount written off for depreciation of cable stores is £2,150 more, and we have also written off from the cost of electric lighting plant and tanks at stations £1,000 more this half year, and charged the cost of land lines at Cadiz and establishing station there, £195, to revenue. The general expenses in London were £8,333, and in 1887 they were £8,169. Some of the items under this head are more and some less, the net difference being an increase of £164. The working expenses at stations were £62,786 against £60,674, or an increase of £2,112. The principal increase under this head is maintenance and renewals of electrical instruments £1,093, and stationery and printing £660. The first increase is explained by a number of new instruments having been sent to Porthcurno, Suez, Aden, Bombay, and the Levant, and a larger amount of stationery was supplied owing to the increase in the number of messages and general business of the Company. I may also remark that we have opened a station at Cadiz, which involved some expense, but which will be a feeder to our general system. The expenses attending repairs and renewals of cables amounted to £38,412 against £43,903, or a decrease of £5,491, although we have charged under this head the whole cost of duplicating the Zante-Patras section, about sixty miles. Therefore, after charging all expenses, including income-tax, interest on the Debentures, Debenture Stock, and Preference Shares, we are able to pay a dividend of 5 per cent., and a bonus for the year of 1 per cent., making together 6 per cent. per annum, and carry to general reserve fund £75,000, carrying forward a small balance of £884 to the next account. It will be seen on reference to page 6 of the accounts that we have charged the whole cost of triplicating the Porthcurno-Malta cable and extension to Zante to the reserve fund, which is thus left at £342,338, which, with the special reserves stated in the balance-sheet, make the total amount of the reserves £362,606. We have also charged the amount expended on the new screw steamer "Amber" to the maintenance of ships fund. The issue of Four per Cent. Mortgage Debenture Stock to pay off the Five per Cent. Debentures is now complete, and the premium on the issue of the same, £2,366, has been credited to the reserve fund. The Five per Cent. Debentures were re-payable in 1887, amounting to £450,000. I think I need not say that that is a very remarkable instance of the strong position which our stocks hold on the London market, that we have been enabled to issue our Four per Cent. Debenture Stock practically at a premium, and it now stands at a considerable premium. That is the best evidence I can give you of the confidence on the part of the commercial community of London in this undertaking. It will be seen on reference to page 8 of the accounts that the total capital amounts to £5,900,000, and the capital expenditure to £5,965,000. We propose to make arrangements to dispose

Digitized by Google

of the £62,000 Six per Cent. Debentures of the Direct Spanish Company, and when that is complete the capital and the capital expenditure will practically balance. We shall then be able to increase the investments on account of our reserve funds. I may say that all these extraordinary sums—taken partly from reserve and partly from revenue—enables us to keep down our capital expenditure, and I hope to maintain in future a very steady and respectable dividend, at the same time increasing our reserve fund, because that fund is most important in connection with such an institution as this. With a strong reserve fund at our backs our shares can be maintained in the market, and regarded as a good investment, and not as for speculative purposes. We find that men are coming in now and becoming proprietors who years ago would not have considered it an investment in which they could put either their own money or that of trustees. In conclusion, I may summarise the accounts as follows:—The gross revenue is £27,844 more; the balance brought forward from last half year was £16,306 more than in the corresponding period of 1887; and the total expenses, including ships and income-tax, are £3,341 less, so that we are able to place £27,000 more to reserve fund, and to pay £19,000 more (or half per cent. more) bonus than in the corresponding period of last year. Now, gentlemen, I think I have placed before you a most satisfactory statement. Just before coming into the room I referred to the remarks that I made at the last half-yearly meeting. That was one of those pleasant meetings which I personally must remember as long as I live. Very kind remarks were made on that occasion by shareholders at the honour which had been conferred upon me—an honour which I accepted as being connected with the institution by which you have all so long stood I see, referring to the report of the last meeting, that I made certain prophecies. I told you that in all probability, at the pace that we were going, we should be able to pay you the 1 per cent. bonus. That bonus had been taken away for a time on account of the large deductions that had been made in our rates at the Berlin Telegraph Conference. We were forced to reduce our rates. We have, however, recovered our position, and we are able to declare to-day our regular 5 per cent. dividend, with a bonus of 1 per cent. for the year, bringing you back to the point where you stood before we went to Berlin. I think you must regard that as a very satisfactory position to be in. During the last year, too, we have added increased strength to our system by the laying of a third line from Porthcurno to Lisbon, Gibraltar, Malta, and Zante, giving us another important cable; and that makes us independent of the French line through France. While, however, it makes us independent of that line, and we can work without it, we are so anxious to have our work done in a thoroughly efficient and prompt manner that we are still desirous of having that line through France. We have been negotiating for a considerable time with the French Government, but there have been difficulties in the way—difficulties connected with the Channel cable. It was only the other day, I think last month, that the whole of those agreements were settled, and now the Submarine Company's system is merged into the Government system. By that we shall practically benefit to some extent, but it will leave the French people free to deal with us in regard to this line through France. If we can get it on such terms as will be a great aid to us, and facilitate our work, we shall have it; but having laid down this third line that I have mentioned we are made perfectly independent, whether France agrees or not. I think, however, that a spirit is abroad among nations that this great system is now more or less international; while they contribute nothing, they receive the same benefit that England receives from this system. I think that that view is gaining ground so far that I am hopeful in the future that we shall find less difficulty in negotiating with foreign Governments than we did in the early days of this work. We have further evidence of that at this moment in Portugal, where there is a disposition to meet us, and a fair disposition, too. We shall encourage that as far as possible; and you can easily understand that the more feeders we can secure, the more other nations interest themselves in our system, the better for the shareholders. I think I have now pretty nearly told you the whole of our position excepting this: I have told you in my written remarks that we are doing a most satisfactory business at the Cape, but we feel that that system is not as perfect, not as secure, as we should desire it to be. We have only duplicated up to Aden, and a very small portion of our line is duplicated between Aden and the Cape. We are now about completing arrangements whereby we shall secure an alternative route to the Cape, joining our system at St. Vincent, utilising the line lately laid along the West Coast of Africa, giving us an alternate line, and securing a permanency to our Cape traffic, meeting a requirement of the Government, and, in other words, giving us such an independent position that will very materially indeed strengthen the Eastern Company. The Eastern Company is the parent company, and is the owner of a large portion of the South African Company and African Direct Company's shares. The Eastern Company will, to a large extent, control this new system, and when I tell you that Sir James Anderson and one or two others connected with this system will control that system, you will see that it places you in a stronger position than I have ever been able to tell you of at any previous meeting. I may say this, just to show you how rapidly these matters are dealt with. We work in connection with the Eastern Extension Company. They are a large feeder to us homewards, we are large feeders to them outwards. Three weeks ago both cables, which is very remarkable, ceased to speak at the same moment. That was to us an extraordinary event. However, we did not hesitate to take steps at once to have the cables repaired; and I am glad to say that the interruption is now tided over, because one of the cables is repaired, and we expect to hear of the other repair being effected. The Eastern Extension Company took steps and chartered a vessel; in short, the time of interruption and difficulty was met in such a way that the whole thing was put right in the short space of three weeks, and that almost at the other side of the globe. That work was done by the Eastern Extension Company, which is our ally; and of that Company, as you are aware, I am also Chairman. The advantage of working the two companies together is so immense to us both that I mention this circumstance, because if there had been opposing interests we could not have done the work in anything like the time I have mentioned. I think I may now conclude by repeating what I said before—that we have strengthened our position in every way. We have increased our reserve fund, we have paid a large sum towards increasing our cable power, and we have also given you to-day, with all that extra expenditure, a fulfilment of our promise by giving you the bonus of 1 per cent. With these remarks I beg to move:—

"*That the printed report and accounts of the Directors to the 31st of March, 1888, submitted to this meeting, be and the same are hereby received and adopted. That a dividend on the Preference Shares of the Company to the 30th of June, 1888, at the rate of 6 per cent. per annum, be paid, less income-tax, and that, in accordance with the Directors' recommendation, a dividend be and is now declared of 2s. 6d. per share, with a bonus of 2s. per share, both free of income-tax, on the Ordinary Shares of the Company, making, with previous payments by way of dividend on account, a total payment of 6 per cent. on those shares for the year ended 31st March, 1888.*"

The VICE-CHAIRMAN (the Marquis of Tweeddale): I beg to second that.

The CHAIRMAN: If any gentleman has any remarks to make before I put the motion, I shall be glad if he will speak now.

Captain GOODSALL: On which coast is the Bombay cable down? You say in paragraph 6: "The several sections of this Company's cables are in good working order, with the exception of the Aden-Bombay cable."

The CHAIRMAN: I should have mentioned in my remarks that the shore end of one of our Bombay cables has been interrupted. When I say "interrupted," it is limping, it is not working as it ought to work; but we expect when the ship gets to the spot it will be repaired speedily. Meantime, it does not interfere with our traffic except to the extent that we have one cable less.

Captain GOODSALL: Will you inform me the length of cable between Porthcurno and Zante, *vid* Malta, for which you are paying £315,000?

The CHAIRMAN: Will you please finish, and I will answer the questions altogether?

Captain GOODSALL: I should like to know the price you are paying for the "Amber" out of the ships' maintenance fund. You mix it up altogether. That is all that I have to say.

The CHAIRMAN: The distance is 2,728 miles from Porthcurno to Zante. The "Amber" is chargeable to our maintenance ships' reserve fund, and the amount expended to 31st March last was £29,000 odd.

Captain GOODSALL: Thank you.

The CHAIRMAN: The resolution has been moved and seconded; those in favour of it please hold up their hands. To the contrary. Carried unanimously. That is the only resolution I have to put to you to-day, and I am pleased to find that you are so well satisfied with it.

Mr. NICHOLSON: Before we separate I think we may pass what with us is not a formal vote—a vote of thanks to the Chairman, Directors, and staff for the very able way in which the affairs of our Company have been conducted. That resolution requires no recommendation from me, and I beg to move it.

Mr. HURST: I have great pleasure in seconding that, because I think the report of the Directors and the explanation of the Chairman are extremely satisfactory. Everything we have heard to-day should make us thoroughly pleased with our property. There was one remark in particular that I wish to note that is equally satisfactory—that is, when he spoke of these shares being held very much now as an investment. It would appear that the idea of speculation attaching to the shares is passing away, and that our undertaking is now regarded as a positive and sound security.

The SOLICITOR (Mr. Burt): I will put that to the meeting:—

"*That the best thanks of the meeting be given to the Chairman, the Board of Directors, and the staff for their able and successful conduct of the Company's business during the past year.*"

Those in favour of that please signify the same in the usual manner. To the contrary, if any. Carried unanimously.

The CHAIRMAN: On behalf of my colleagues and myself I have the greatest possible pleasure in returning thanks. As to our staff, it has always been our pleasure—and not only our pleasure, but our duty—to have on our staff the very best men we can find to do the work. We have treated those men generously, and we have had many acknowledgments of that. It will always be our duty to maintain on our staff men of the highest qualifications to fulfil the very onerous duties entrusted to them. On behalf of my colleagues and myself, and the staff, I beg again to return you my best thanks.

The proceedings then terminated.

The Globe Telegraph and Trust Company (Limited).

Report of the Directors to be presented to the fifteenth ordinary general meeting to be held this day (Friday), at 2 p.m., at Winchester House, 50, Old Broad-street, London, E.C.

2. The net revenue of the Company for the year, after deduction of expenses, amounts to £168,053. 13s. 2d., which, with the balance of £1,442. 6s. 8d. brought forward, make a total of £169,485. 19s. 10d. From this amount there has been distributed the sum of £114,023. 14s. 9d. in interim dividends, leaving an available balance of £55,472. 5s. 1d.

3. The Directors recommend payment of a final dividend for the year of 3s. per share on the Preference Shares, and of 3s. per share on the Ordinary Shares, making, with the former distributions, a total dividend for the year of 6 per cent., less income-tax, upon the Preference and 3½ per

Digitized by Google

cent. net upon the Ordinary Shares (against 2½ per cent. for the preceding year), and carrying forward a balance of £2,107. 1s. 3d.

4. The Directors hope that before long an arrangement will be made whereby a remunerative tariff may be established for Atlantic messages.

5. The Imperial German Government having acquired the lines of the German Union Telegraph Company of Berlin, the German Union Telegraph and Trust Company will cease to exist at about the end of the present year. This is a measure in furtherance of the acquirement of the Channel cables by the Governments. The Board have reason to believe that the return on the capital of the German Union Telegraph and Trust Company, in which this Company holds largely, will be about par, while on the Preference Shares of the German Union Telegraph Company of Berlin held by this Company there will be a profit on capital account of about 20 per cent.

6. In pursuance of agreements made between the Western and Brazilian Telegraph Company and the London Platino Brazilian Telegraph Company, the shares of the latter Company have been exchanged for an equivalent in the Western and Brazilian Telegraph Company's Shares. The Board hope that the revenue on this item in their accounts will be augmented in the future.

7. During the past financial year a further quantity of 2,000 Ordinary Shares of £15 each of the Western and Brazilian Telegraph Company Shares have been acquired in exchange for Preference and Ordinary Shares of this Company.

8. Fifty-nine shares of the German Norwegian Telegraph Company have been drawn for amortisation, and paid off at par, less exchange.

9. In conformity with the Articles of Association, the Marquis of Tweeddale and Henry Daniel Gooch, Esq., two of the Directors, retire, but, being eligible, offer themselves for re-election.

10. The auditors, Mr. John George Griffiths, F.C.A. (Messrs. Deloitte, Dever, Griffiths and Co.), and Mr. William Griffith, B.A., barrister-at-law, also retire at the meeting, and offer themselves for re-election.

NEW COMPANIES REGISTERED.

THE SUBMARINE MINING AND TORPEDO EXPLOSIVES COMPANY (LIMITED).—Registered by Saunders, Hawksford, Bennett and Co., 68, Coleman-street, E.C. Capital £30,000, divided into 30,000 shares of £1 each. Object, to acquire from Messrs. Gibbons and Fox all patent and other rights belonging to them in torpedoes and submarine mines, under an agreement dated July 10, 1888, and made between Charles J. Fox of the first part, Joseph Pannell Gibbins of the second part, and Alfred Wright, as trustee for the company, of the third part; to carry on the trade or business of manufacturers of torpedoes, and all materials, substances and things incidental to the manufacture of torpedoes and submarine mines, or the packing and storing, firing, and carrying on the disposition thereof. The first subscribers are:—

	Shares.
F. Thorn, 8, Addington-road, W.	1
T. Heyworth, Newport	1
H. D. Sandeman, Fernlee, Worlingham, Kent	1
J. W. Baine, Howard House, Harrow	1
W. H. Amos, 124, Burrage road, Plumstead	1
J. S. Anderson, 36, Wellesley-road, Croydon	1
T. Large, 8, Coburg-road, Teddington	1

The first directors shall be Frederick Thorn, L. Heyworth, H. D. Sandeman, and J. W. Paine. The qualification shall be the holding of not less than 250 shares in the capital of the company. The remuneration to directors shall be the sum of £500 per annum, with an additional sum of £150 to the chairman.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended July 20th, 1888, amounted to £4,633.

CUBA SUBMARINE TELEGRAPH COMPANY.—After providing for the dividend on the Preference Shares, and placing £6,000 to the reserve fund, a dividend on the Ordinary Shares at the rate of 9 per cent. per annum is proposed, leaving £1,195 to be carried forward to the current half year's account. A year ago the dividend was at the rate of 8 per cent.

SUBMARINE TELEGRAPH COMPANY.—The accounts of this company for the half year ended June 30th, 1888, submitted to the Board, show a balance, subject to audit, which enables the directors, after adding 15 per cent. of the gross receipts to the reserve fund, to recommend a dividend at the rate of 13½ per cent. per annum.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended July 20th, 1888, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company, were £3,924.

CRICKET.

Eastern Telegraph Company v. Kenneth Anderson and Company.

This match was played at Beaufort House on Saturday, the 14th inst. The Eastern won the toss, and commenced to bat in a very bad light; but notwithstanding this they knocked up the very creditable total of 126. Penney and Wells both batted well for 34 and 31 runs respectively, while Richardson played a dashing 17 (not out). Gurney bowled very steadily, his analysis being five wickets for 36 runs. Messrs. Anderson's representatives then wielded the willow, but were all dismissed for the small total of 19, and consequently had to follow on. Their second venture realised 39 runs, leaving the Eastern Company victorious by an innings and 68 runs. For the Eastern, M'Millan obtained 7 wickets for 6 runs, and Chisholm 3 wickets for 11 runs. Great zest was given to the game by Mr. Kenneth Anderson presenting a handsome bat for the highest score in the match, and a ball for the best bowling analysis. The former was won by A. O. Penney, and the latter by J. G. M'Millan, both of the Eastern team.

Mr. Hibberdine acted as captain for the winners, and Mr. Alex. Jack for the losing team. Scores:—

EASTERN.—J. G. M'Millan, b Jack, 8; Chisholm, c Gardiner, b Gurney, 8; S. Wells, c Jack, b Gardiner, 31; A. O. Penney, b Gurney, 34; W. Macdonald, b Gurney, 12; T. Richardson, not out, 17; E. D. Payne, c Granger, b Gurney, 2; Lacy, b Launders, 0; J. Wells, b Gurney, 0; A. W. Donaldson, b Launders, 1; W. Hibberdine, run out, 4; extras, 9—Total, 126.

KENNETH ANDERSON AND CO.—First Innings: G. C. Hawes, b M'Millan, 0; A. Gardener, c Richardson, b Chisholm, 3; A. Jack, b M'Millan, 1; H. Gurney, b Chisholm, 0; Major Granger, c Richardson, b M'Millan, 4; C. Job, b M'Millan, 0; Gowenlock, b Chisholm, 7; A. J. Launders, b M'Millan, 0; J. Lang, b M'Millan, 1; J. Strudwick, not out, 0; E. Smith, b M'Millan, 1; extras, 2—Total, 19. Second Innings: G. C. Hawes, b Chisholm, 0; A. Gardener, b Chisholm, 9; A. Jack, c Penny, b Chisholm, 3; H. Gurney, c Chisholm, b M'Millan, 0; Major Granger, b Penney, 0; C. Job, c Chisholm, b M'Millan, 2; Gowenlock, c Chisholm, b M'Millan, 11; A. J. Launders, b M'Millan, 8; J. Lang, b M'Millan, 0; J. Strudwick, b Chisholm, 0; E. Smith, not out, 3; extras, 3—Total, 39.

ERNEST NOEL, Esq.
Sir JOHN PENDER, K.C.M.G.
J. DENISON PENDER, Esq.
The Right Hon. LORD SUDELEY, P.C., F.R.S.
LEOPOLD SALOMONS, Esq.
JOHN C. SALT, Esq.
C. A. WHITMORE, Esq., M.P.

Offices—**WINCHESTER HOUSE, OLD BROAD STREET, LONDON, E.C.**

The principal objects of the Corporation are:—

1. Performing the duties of Trustee, Executor and Administrator.
2. The Insurance of Bonds, Shares and all other Securities lodged with the Corporation against risks of all kinds.
3. The Issue of Warrants and Certificates against Securities deposited, and making and procuring advances on such Warrants.

The Office of Trustee or Executor is to private persons usually a thankless post, involving much anxiety, time and money, and frequently leads to serious actual loss; whilst death, illness and change of residence necessitate frequent fresh appointments, and consequent expense to the parties interested. The Corporation undertakes all the duties of Executor, Trustee or Administrator for reasonable remuneration proportioned to the work and responsibility in each case.

The Corporation insures existing Trustees and Executors against all risks attending those positions, where the business is conducted by the Solicitors to their Trusts under the supervision of the Corporation, it not being the desire of the Corporation to interfere in any way with the duties of the family solicitor.

The Corporation acts as Trustees for the Debenture Holders in Public Companies.

For terms, &c., application should be made to the General Manager at the Company's Office.

GEORGE PEARSON, *General Manager and Secretary.*

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL SCIENCE, INDUSTRY AND ENGINEERING.

No. 533.—Vol. XXI. FRIDAY, AUGUST 3, 1888. Price 4d.

NOTES.

We are glad to announce that the Organising Committees of Sections A and G of the British Association have arranged a joint discussion on "Lightning Conductors," to be held at the Bath meeting, in September. Mr. W. H. Preece, F.R.S., will open the discussion, and Prof. Oliver J. Lodge, D.Sc., F.R.S., will defend the position he advocated this year before the Society of Arts. The occasion will be looked forward to with the greatest interest, and we anticipate a very instructive debate.

The Metropolitan Electric Supply Company, to which we drew attention last week, closes its lists to-day. Besides the influential names which we then gave as connected with the scheme, the directorate consists of a number of gentlemen who have been associated with electrical industry almost from its infancy. It will be seen by the prospectus that this company is not committed to any particular patents or systems, but leaves itself free to adopt any which promise favourable results. Under such management, and with such a programme, the success of the undertaking is well assured.

The Chelsea Electricity Supply Company, which has also just closed its subscription list, has a healthy appearance which it affords us much pleasure to recognise. Launched under the auspices of three leading electrical firms (the E.P.S. Company, the Anglo-American Brush Company, and Callender's Bitumen Telegraph Company), with directors from each of these companies on its own Board, and with a committee of consultation consisting of Messrs. Callender, King and Raworth, it is at least certain that the management will know thoroughly well what it is about, and will be quite competent to select the most suitable means of doing it. From a technical point of view the enterprise presents many features of considerable interest. The system to be adopted is that of battery transformers in sub-stations, with the automatic charging and discharging switch designed by the engineers of the E.P.S. Company. Save for the ill-fated Colchester enterprise—which was altogether before its time—this will be the first occasion on which the battery sub-station method of distribution has received a fair trial, and we shall look forward to it as affording a crucial test of the capabilities of the system. If it cannot be made to succeed in the present hands, it must clearly be useless for anyone else to try it for a long while to come. However, there is every reason to anticipate that the Chelsea Electricity Supply Company will be a thoroughly successful enterprise.

By a singular coincidence the same week which has witnessed the public advent of two of the most extensive and most promising electric lighting schemes that have yet been launched has witnessed also the final obsequies of a pair of those wild and worthless ventures which marked the period of inflation of six or seven years ago. The total loss of capital in these two concerns alone amounted to no less than £97,049. Compared with the mechanical skill and knowledge of the science which is now brought to bear upon the problem, the companies which were to have illuminated the world in 1883 may practically be said to have possessed not a single qualification for commercial success. Their untoward fate, it is to be hoped, will act as a warning to any rash and ignorant speculators who may be tempted into the field by the recent successes of better informed and more competent undertakers.

Referring again to the Metropolitan Railway project, and on the principle of *audi alteri partem*, we have pleasure in publishing the opinion of the secretary of the New England Western Electric Light Company, which we find in a letter addressed to our Boston contemporary, *Modern Light and Heat*, especially as this is the first occasion in which we have met with any criticism favourable to the scheme coming from a technical quarter. After referring to the severe handling which it appears that the proposals have received from the *Boston Herald* (surely a competent critic!), the writer proceeds, in somewhat questionable English, as follows:—"The sole reason is because no one has been able to put into use with accumulators a motor of sufficient economy to do its work effectually, with the small current the batteries could give off without damage to themselves, they [query, who?] did not propose to condemn their motors and so did condemn the accumulators. The New England Western Electric Light Company has been running for more than a year a car at Cambridge with 120 cells of accumulators, making 12 miles an hour on levels and three to five up the steepest grades, and never drawing over the 35 amperes, the limit of the batteries without heating, and the cells are as perfect to-day as when first put in, and this at a cost of $3 for 80 miles run, this sum including 10 per cent. on the whole charging and motor plant. These are facts that can be proved; the storage system is a success in this instance and as cheap a method as has been devised and all overhead, underground connections are unnecessary, it can be put in any present well equipped horse railroad.

Digitized by Google

If the tracks are in poor condition they should be made strong and that is wise even with horses. There is lots of dust thrown into the air to cover incompetency."

Now, in spite of its batteries which "do not heat," its general incoherency, and total irrelevance to the question of the Underground Railway traffic, we nevertheless find something of distinct value in this communication. So far as we are aware, this is the first record of twelve months' service with accumulators used for traction in which it has been possible to claim that the cells have stood the test triumphantly, and have come out "as perfect as when first put in." Then as to the price! *C'est magnifique, mais ce n'est pas le commerce;* at least we know that it cannot be done in this country, if that is any criterion. One penny three farthings per car-mile (including 10 per cent. depreciation on the plant) would make even a North Metropolitan Tramway director's mouth water. Seriously, however, we are pleased to learn that some financial success has been attained with the battery system in the States, and we shall be glad to have authentic details.

In our issue of June 29th, under the title of "Delany's Improvements in Cable Telegraphy," we described an ingenious modification of the Morse key designed for transmitting dot and dash signals at the ordinary rate of hand signalling over long cables. A fortnight later Mr. F. Higgins pointed out in our correspondence columns that twenty years ago Sir Charles Wheatstone and Mr. Augustus Stroh had designed a key of the same description, and that it had been successfully employed upon the Amsterdam cable. We have since ascertained the date of the patent specification in which this invention is described, and we now publish an extract (with illustrations) in another column, from which it seems sufficiently clear that Mr. Delany's idea belongs to the extensive category of "re-inventions." Whether it is actually possible to increase the carrying capacity of a long cable by substituting this method of working for the Thomson recorder, is, perhaps, open to question. Seeing that the technical officers of the cable companies can hardly fail to have been acquainted with the Wheatstone and Stroh patent, the device, if really efficient, would almost certainly have been in use long ago.

The remarkable experiments with high tension electricity described by M. Gaston Planté in a fascinating book which we review in this issue, recalls to our recollection an experiment which we once saw Mr. Mordey perform at the Brush Company's works. This consisted in obtaining an arc between the surface of a solution of common salt placed in a basin and a carbon electrode brought immediately over it. The experiment is a very brilliant one, the evolved gases recombining in the form of vivid flames, which are of course coloured an intense yellow by the sodium. We do not, however, recollect that the arc assumed the globular form described by M. Planté in similar experiments.

Our New York letter discloses the fact that the battle of Alternating *versus* Direct Currents is being fought out in that city with the utmost determination. The threatened invasion of the Westinghouse forces has evidently aroused the direst apprehensions on the part of the companies who at present hold the field. It is no longer a question of discussing the *pros* and *cons* in amicable conclave, but of fighting tooth and nail for the favour of the Board of Electrical Control. At the special meeting of the Board held to consider the question a formidable array of testimony was adduced in support of the assertion that the prevalent apprehension of a special danger attaching to alternating currents is entirely without foundation. The simple fact that in all the eighty-two stations now operating this system in the United States no fatal accident has yet occurred affords in itself a remarkably strong presumption in favour of this view, and, moreover, the Westinghouse Company were able to bring evidence of a positive as well as a negative character. No decision has yet been pronounced by the Board, and apparently the opposition has yet to deliver its reply. For our own part, we have become convinced—and we know many electrical engineers who adopt the same view—that if any difference in the degree of danger to life exists, it is the continuous current which is the more dangerous of the two.

Nothing transpired at the half-yearly meeting of the Submarine Telegraph Company with regard to the impending purchase, except that the chairman spoke of its transfer to the "Governments of the countries" in the plural; from which it may be inferred that the British Government will not alone become the possessor of the company's cables. No hint as to the price to be paid was let fall; but it is gratifying to note that a very valuable property is to be bequeathed to the company's successors, and that the company itself is retiring with golden laurels. Thirteen and a-half per cent. dividend, with fifteen per cent. added to the reserve fund, and a balance carried over, is a very respectable ending to a long and prosperous career.

Some of our excellent American contemporaries have recently taken to printing short and pithy extracts from the sayings or writings of leading men in the electrical world, under the generic and expressive title of "Pointers." As examples of the method we may take this of Gisbert Kapp:—"If secondary batteries were good enough, I should never dream of putting down alternating transformers, but I have never seen a good battery;" or that other of Thomas D. Lockwood (of Telephonic fame)—"What possible avail can it be, if the right thing is not done in the right way, by the right man at the right time?" And again, a Pointer from W. M. Mordey, "We seem to make all the improvements, but the Americans make all the money"; or, yet once more, J. Swinburne's wise saying, "Inaccurate calibration is a much more common fault in measuring instruments than bad design." Lastly, we will wind up with this of Francis B. Crocker—"It is well enough, perhaps, to designate volts obtained by chemical action as equi-volts, but I do not know any reason for it. Really, these equi-volts are just plain, ordinary, North American volts." On this we are constrained to remark that Mr. J. T. Sprague says that the "equi-volt" is not a common or garden volt, but a unit of energy, and we think that Mr. Sprague ought to know, if any one does.

Digitized by Google

The Lighting of the City.—We understand that at an early date the question of lighting the City by electricity will again come before the Commissioners of Sewers.

The Graphophone.—We hear that Mr. Henry Edmunds (of the Cadogan Electric Light Company) is bringing some graphophones back from the States, and will probably read a paper on the graphophone before the British Association at Bath.

A Telegraph Wire Struck by Lightning.—A wire of the Exchange Telephone Company's system at Bow was struck by lightning and fused in the centre of a span, during a thunderstorm on Monday afternoon last. The conductor was of copper, ·083in. in diameter.

Photographs of Lightning—M. Trouvelot has secured a photograph of a remarkable lightning flash which occurred on the 24th June. The principal flash divided itself into four branches, and these again are subdivided into no less than thirty-seven distinct streams.

The Chilian Telegraph Service.—In the address of President Balmaceda, at the opening of the Chilian Congress, reference is made to the introduction of a new measure, by which it is proposed to organise the postal and telegraph services under one board of management.

Metropolitan Electric Supply Company (Limited).—It will be seen by our advertising columns that the above-named company has issued its prospectus, the leading features of which we foreshadowed in an editorial note last week. The subscription lists open and close this day (Friday).

Athens.—The Edison Continental Company has undertaken the electric lighting of the forthcoming Exhibition at Athens, at which the exhibits destined for the Paris Exhibition of 1889 will be shown. The installation will comprise two 300 ampere dynamos, 50 arc lamps, and a few incandescent lamps.

Lubricators.—We learn that the Dee Oil Company, of London and Saltney, have secured the whole of the Admiralty contract for cylinder oil, 1888-1889. This contract is the largest ever given out for high-class oil for internal lubrication by the Lords' Commissioners.

Electric Light on a Swedish Railway.—Electric lighting has been successfully tried on the Skane-Holland Railway, in Sweden. The lamps are fed from an accumulator in the luggage van. The installation has been effected by Messrs. Edwin Audrén and Co., Gothenburg, and it is intended to fit all the express trains between Christiania and Helsingborg.

The Burman Land Lines.—The *Indian Engineer* says that the telegraph line from Yunan to Moulmein will soon be completed, the constructors and materials having reached the latter place with a view to working backwards. When this is done, about 80 miles more in a straight line will connect the Chinese Government telegraphs with the Indian Government telegraphs.

Paris.—Our Paris correspondent informs us that the Municipal Council has voted funds for the creation of a municipal central lighting station at the Halles Centrales. The examination of the proposals for establishing central stations in different quarters of the town, which have been received from several electrical firms, has been postponed in each case until October next.

The 1889 International Congress of Electricians.—The Comité d'Organisation of this Congress met for the first time on Tuesday, 24th July, and elected an Executive Committee. The following officers were nominated:—President, M. Mascart; vice-presidents, MM. Gariel, Fontaine, and Lippmann; treasurer, M. Lemonnier; secretaries, MM. Hospitalier de Nerville, Hillairet.

Crompton and Co. (Limited).—The conversion of the well-known firm of R. E. Crompton and Co. into a limited liability company is announced this week, with a capital of £140,000. We understand that the issue of a prospectus will not at present take place, but we are informed that a large amount of the capital has already been privately subscribed by the directors and their friends.

The City Commission of Sewers.—At the last meeting of the Commission of Sewers, notices were received from the Metropolitan Electric Supply Company, and from the London Electric Supply Corporation, giving notice of an application to the Board of Trade in the ensuing Session, for a provisional order for power to supply electricity for lighting and other purposes within the city.

Birmingham Central Electric Light and Power Station.—Messrs. Chamberlain and Hookham have appointed Mr. Norman T. Gray engineer to this scheme. The price at which the electricity is proposed to be supplied has now been fixed at 8d. per unit, which is equal to a little less than ½d. per hour for incandescent lamps of 18 candle-power, and about 4d. per hour for arc lamps of 2,000 candle-power.

The Waterhouse Arc Light System.—We learn that this system, which is well known in the United States, is being introduced into England by Messrs. Shippey Brothers (Limited), who have been appointed agents for the Waterhouse Company, whose works are situated at Hartford, Conn., U.S A. The company guarantees to light ninety 1,700 candle-power lamps, 2,000 candle-power nominal, with an expenditure of 50 horse-power.

A Chapel Collection on Behalf of the Electric Light.—The *St. Pancras Gazette* says that the Rev. F. B. Meyer, B.A., minister of Regent's Park Chapel, Park-square East, at the close of his discourse on Sunday evening, made an appeal for funds to light the church with the electric light during the winter months. The building was thronged with the usual large congregation, and the response to the preacher's appeal was a very liberal one.

The German Union Telegraph Company of Berlin.—The German Government have exercised the option which they reserved to themselves under their agreement of assuming the property of the line on and from 1st July. The effect of this will be to give to the shareholders an adequate return, because it is on the basis of their best half-year's receipts. The line is now administered by the German officials. It is expected that the return of the capital will be paid part in January and the balance shortly after.

The Great Western Railway Electric Lights.—The members of the Inventors' Institute paid a visit on Saturday last to the Great Western Electric Lighting Station at Paddington, under the guidance of Mr. Spagnoletti. This plant now comprises 4,000 incandescent and 100 arc lights. Mr. Spagnoletti said that the electric lighting had put an end to the very frequent accidents which formerly occurred to the shunters and goodsmen and also to a large amount of damage to the company's trucks and rolling stock, everything being now accomplished at night with as much precision as in the day time.

Wellington. N.Z.—The Corporation of Wellington, New Zealand, have accepted the tender of the Gülcher Company to light that city by electricity. It is proposed to use incandescent lamps and to drive the machinery by water power obtained from the city waterworks. The contract is for 480 Edison-Swan lamps

Digitized by Google

of 20 candle-power each, each lamp to be lit from dark to dawn. The price is £1,750 per annum for the first five years, the company offering to run the undertaking for a further period of five years at £1,600 per annum if the council decide not to purchase the plant at the end of the first period.

The Wells Light.—Our readers will be somewhat disappointed to learn that the works of the Manchester Ship Canal are not to be illuminated by electric light. Its place has been taken by the "Wells Light," in which ordinary mineral oils are burnt, but which seems to be an improvement upon the Lucigen light. If the improvement be of a substantial character, and the cost as little as is claimed by the inventor, it is probable that the Wells light will prove a formidable competitor for the lighting of contractors' works and outdoor spaces where the heat and dirt of a naked flame is permissible.

Valencia, Spain.—Spanish advices refer to the early inauguration in Valencia of an important central station for the supply of electric light. The installation is to consist of 16 steam engines of 100 horse-power each, 16 dynamos for 1,200 lamps of 10 candle-power, 12 multitubular boilers of 108 horse-power, three pumps for raising water, and 12 small pumps for feeding the boilers. The Spanish paper from which we take the information does not mention the name of the contractors, but from the nature of the facts stated the installation looks very much like one we referred to as being under consideration some time ago.

Bournemouth.—At the last meeting of the Bournemouth Town Council an application from the local electric light company was read, asking permission to erect in the borough iron standards similar to those erected by the telephone company in Bournemouth, which, the application stated, "had a nice appearance, and were only four inches at the base, not so wide as an ordinary lamp-post." The town clerk suggested that the matter should be allowed to stand over until the quarterly meeting of the Council in August, and, in view of the fact that the Electric Light Company are going to send in a tender for lighting the town by electricity, this was agreed to.

Mexican Telegraph (Cable) Company.—Advices from the City of Mexico state that the half-yearly report of this company—that is to say, for the six months ended June 30th—shows operating expenses 17½ per cent., against 23½ per cent. in the first half of 1887. The figures compare as follows :—

	1st January to June 30.		
	1888.	1887.	Inc. or Dec.
Earnings	$168,582 ...	$130,173 ...	+ $38,409
Expenses	29,694 ...	30,704 ...	- 1,010
Surplus	$138,888 ...	$99,469 ...	+ $39,419

A quarterly dividend of 2½ per cent. was declared in June.

The Cost of Copper in the Edison System.—In a recent Paper by Mr. G. H. Bliss, read before the Chicago Electric Club, the following illustrations of the cost of copper per lamp in the Edison system are given :—"I will give one or two examples of what the actual cost is for copper in a couple of Edison stations now in process of installation. For one installation which provides 100 street lamps scattered over an area of 1½ mile square, and 500 lights for stores, residences, and churches in a mile square, the entire cost of copper, at 20 cents per pound, is $3,000, or $5 per lamp. For another installation where 100 street lamps are scattered in one area two miles square and 800 inside lights in an area about a mile square the entire cost of copper, at 20 cents a pound, is $3,102, or $3.44 per lamp."

Hastings.—The *Hastings News* says :—"The local electric light company is steadily pushing ahead and extending its business. Much more could be done if the townsfolk would encourage the company by putting more capital into the concern and adopting the electric light for private houses, workshops, and other places. Nearly all the hotels are now supplied with the incandescent lamps, and the Alexandra Hotel will increase its improvements by having about one hundred lights on the circuit. Some of the larger boarding houses in the town are also trying the new illuminant. Considering how healthy and clean and comparatively cheap the electric light is, it is somewhat surprisising it is not more used in large establishments."

Presentation to Mr. J. T. Crowe, of the Eastern Telegraph Company's Staff.—In view of the approaching marriage of Mr. J. T. Crowe, of the head office staff of the Eastern Telegraph Company, his friends at Winchester House, Old Broad-street, took the opportunity of showing their regard by presenting him with a handsome silver-plated tea and coffee service with salver to match. The latter bore the following inscription :—"To John Tudor Crowe, Esq., on the occasion of his marriage, August 16th, 1888. Presented by the head office staff of the Eastern Telegraph Company, London." Mr. W. T. Ansell in making the presentation expressed in a few appropriate words the hopes of those present for Mr. and Mrs. Crowe's future welfare and happiness.

The Telephone in the West of England.—The Western Counties and South Wales Telephone Company are about to embrace in their wide spreading net another group of Devonshire towns, including Torquay, Paignton, Newton Abbot, Totnes, Ivybridge, Tavistock, and Horrabridge; and to establish in each of those places call offices. These lines will also be placed in connection with the existing exchanges at Plymouth, Stonehouse, Devonport, Mutley, Plympton, and Marsh Mills. This is a bold experiment, for it involves a large expenditure, and the population of the district is not remarkably dense. But it will enormously increase the value of the Plymouth exchanges to business men, and we trust that it will result in a very considerable increase in the number of subscribers.

Bath.—At a meeting of the Surveying Committee of the Bath Town Council, this week, the Clerk reported the receipt of a letter from the Town Clerk officially stating that the Council had resolved to light certain streets of the city by electricity, and that the arrangements were left with the Surveying Committee. The Mayor suggested that a special Electric Lighting Committee should be appointed. He thought it would be best that no gentleman should be placed upon it who had any pecuniary interest in the gas company or the electric lighting company. Mr. Sturges submitted a list of names, but it was pointed out that several of them were not on the Surveying Committee, and that, therefore, that meeting could not appoint them. Mr. Sturges then proposed the following names :—The Mayor, Alderman Gibbs, Captain Franklin, Messrs. Moger, Collins, Ricketts, and Sturges.

Science Schools.—On Friday last Mr. A. Acland asked the Chancellor of the Exchequer whether the Treasury would be willing to sanction the removal of the restriction on building grants for science schools which made it one of the conditions of grants in aid to such schools that they should be built in connection with a school of art, aided by a Department building grant.—The Chancellor of the Exchequer said he must at present answer the question in the negative. Great expenditure was being pressed upon the Government in connection with technical schools, grants for colleges, and for the development of scientific and technical education. The Government was in sympathy with the movement, but it was necessary to

Digitized by Google

look at the question as a whole and to bring all these schemes together, and then to see in what order and to what extent these claims could be met.

Important Installation at Birmingham.—The Birmingham Corporation Street Estate Company, who are building a large block of shops and offices in Corporation-street and Martineau-street, have decided to light their new buildings with electric light. There will be twenty shops and sixty-four offices in the block, which will be fitted with incandescent lamps, and the tower will be surmounted with a powerful arc light. The dynamos and the electric fittings are being supplied by Messrs. Ellwell-Parker, of Wolverhampton, and the engines, which are compound and of a semi-portable make, are being built by Messrs. John Fowler and Co., of Leeds. The whole of the electric machinery and fittings are being erected under the supervision of Mr. T. C. Sharp. We understand that provision will also be made to supply the electric light to some of the adjoining business premises.

Electric Light Signals.—The Conz system of incandescent lamp signals has recently been tried on the U.S.S. "Atalanta," at Annapolis. Three pairs of lamps, 500 candle-power Edison incandescent, each pair white and red, were secured in sockets on the sides of a block of wood; the three blocks were then screwed on a 12ft. piece of moulding and hoisted aloft. The lamps are capable of fourteen different combinations of signals, no two lights in any one of the three pairs being alight at the same time. The lights are manipulated from a switch-box in the pilot house. This switch-box is a brass cylinder 5in. in diameter, with fourteen glass discs on the dial face corresponding to the fourteen signals. An index moves round the dial face, and when it is over the desired disc a handle in the centre is pulled and the circuit closed through the proper lamps. The box also has an offset to contain an electric lamp to illuminate the discs from within.

The Electrolytic Production of Magnesium.—M. de Mongelas has lately devised a process for obtaining magnesium by electrolysis. An alloy of magnesium is first obtained in the form of an electrolytic deposit. The bath consists of a concentrated solution of chloride of magnesium, combined with an equally concentrated solution of the chloride of any other metal except aluminium. The solution preferred is one part of chloride of zinc and two parts of chloride of magnesium. The two solutions mark 18° on the Beaumé scale. Good results are obtained by using the electrolytic bath as the battery. The external jar contains the double chloride solution and the copper cathode, the amalgamated zinc anode is placed in dilute sulphuric acid. The zinc is deposited in a "spicular" or "arborescent" form, and the magnesium in granular crystals. This alloy is then washed, dried, and crushed, and finally melted in a crucible containing chloride of sodium. The zinc volatilises and leaves pure magnesium.

The Westinghouse Machine Company in Italy.—The Westinghouse Machine Company of Pittsburg, U.S.A., is endeavouring to extend its operations in Italy in machinery for driving electric light dynamos. The company, which was founded in the year 1881, has an agency in Paris, and has upwards of forty engines already in work in France. In Italy the company has not hitherto been directly represented; but a Paris correspondent informs us of the arrival last week of Mr. J. B. Thomas, a representative of the company, who is *en route* for Italy for the purpose of founding agencies of the company. In an interview with Mr. Thomas our correspondent learned that that gentleman's operations will in the first place be principally confined to Rome and Turin. As the object of the company is to extend the employment of the Westinghouse machine for electrical installations in Italy, we may state that, according to our Paris correspondent, the company has made up to the present time about 4,000 engines, of an average of 45 horse-power. The company has 13 sizes of standard engines, varying from 5 horse-power to 250 horse-power, and is now developing the manufacture of compound engines from 6 horse-power up to 600 horse-power. Compound engines of 150 horse-power are already at work.

Gas Pipes Damaged by Lightning.—Mr. J. Best writes to the *Journal of Gas Lighting* as follows:—"A singular occurrence took place at St. Ives (Hunts) on Wednesday last. A thunderstorm passed over the town, and the lightning struck the premises of Messrs. Coote and Sons, coal merchants. Their spacious office is lighted by copper ventilating Argand gas-pendants; the products of combustion being conveyed through the ceiling into the roof. The electric current descended the ventilating shaft of the gas-burner over the desk of the cashier (who was fortunately absent at the time), and made its exit by the office door, which was open. No damage was done here. The adjoining house is occupied by one of the clerks; and there a gas-pipe was melted and the gas ignited. From an inspection made here, the electric current was conveyed into the roof of the dwelling house by the spouting, which is coupled up by a zinc pipe to convey the rain water to a tank under the roof. A ¾-inch lead pipe is brought from the tank down through a bed room and into the scullery, and carried partly round the scullery near the ceiling, crossing at right angles, and so as to touch a ½-inch composition pipe which conveys gas to a bracket. Here the gas pipe was fused, and the gas ignited. There is no chimney in the scullery or in the bed room above. No other damages to the premises could be traced. I shall be glad to learn whether any of your readers have had similar experiences."

The Copper Market.—We take the following from the *Daily News* of yesterday:—"At last the copper syndicate has the satisfaction of observing that the deliveries in France and England are on the increase. Last month the deliveries, according to Messrs. Merton's statistics, were 9,766 tons, having been little over an average of 5,500 tons per month during the previous six months. Earlier in the year the rise in the price of copper had its natural effect of causing consumers to hold off from the market as long and as much as possible. At length, however, deliveries have got back to a normal rate, and even somewhat beyond. For the past twelve months the average monthly deliveries of copper in France and England has been 8,031 tons, while for the previous two years the monthly average was about 7,750 tons, so that the deliveries last month were large and not small by comparison. At the same time stocks in England and France and on passage from Chili and Australia are put at 75,412 tons, being nearly half as much again as at this time last year, and about 15,000 more than the average stock in the year 1886. During the last seven months the stock has been increasing at the rate of five thousand tons per month, and unless the deliveries are maintained at something like the rate reported for July, the syndicate may be in trouble either next year or soon afterwards. It is remarkable that, notwithstanding the increased consumption of copper during July, the visible supply increased by 3,169 tons for the month."

Electric Traction on the North Metropolitan Tramway.—At the 37th half-yearly general meeting of the North Metropolitan Tramways Company, held on Wednesday, at the Cannon-street Hotel, Mr. George Richardson, who presided, stated that the Directors had for some time had under their

Digitized by Google

consideration the adoption of some motive power for propelling the company's cars. Five years ago electricity was proposed to them by a company, who forwarded them an engine, but it proved unsuccessful. The next attempt was made two years ago, when the Elieson Company brought their system to the notice of the company, and an arrangement had been made with that company for working cars on the Romford road. Six engines had been made by that company at the shed which had been set apart for the purpose by the North Metropolitan Company; but more room had now been given by them elsewhere to the Elieson Company, in order that their system might be brought more fully into use. The price at which they had contracted was 4½d. a mile, whereas it cost them 5d. a mile with horse-power. They had also arranged with the Electric Traction Company for working their electric combined engine on the Barking-road. The trial had proved satisfactory, and their engine had been approved by the Board of Trade. The charge was also 4½d. a mile. They hoped that electricity would prove as satisfactory as had been expected. In the United States there were 60 street electric tramways.

Electric Traction on the Metropolitan Railway.—At the half-yearly general meeting of the proprietors of the Metropolitan Railway Company on Friday last, Sir E. W. Watkin said that "one interesting feature of the half year had been the progress that had been made in preparing for the construction of a locomotive engine which will go by electricity. When the engine was completed they proposed to try it on the northern parts of the line if they found it to answer. The conditions were that the locomotive shall be worked as economically and, to use a mechanical term, have a life as long as the ordinary locomotive. These conditions fulfilled, they proposed to substitute gradually a locomotive that made no sulphur, no steam, no smoke, for what would then be the old-fashioned locomotive engine. Now, he knew that people, he would not say had chaffed, but had rather smiled at him when he told proprietors that he thought it their duty to try this experiment; but the experiment had been at the expense of the Electric Traction Company. It was rather a hard bargain for them, but if there was success it would, no doubt, be an immense advantage to this and all underground railways. With regard to the power itself, Mr. Richardson, chairman of the North Metropolitan Tramways Company, had said that the experiments had shown that the motive power of the Electric Traction Company was the best traction power that had been brought before the public. He (the chairman) was told that practically the same words were used—of course, not officially—by General Hutchinson, the distinguished railway inspector to the Board of Trade."

The Electric Lighting Question and the Paddington Vestry. We extract the following sensible letter from the *Paddington Mercury*:—"Gentlemen: I am glad that at last you are moving in the matter of the electric light question. I cannot understand why you have not moved a good deal sooner. It seems to me a pity that you should be so slow to take action in matters affecting the public welfare and convenience, and so quick in those things which bring but little public advantage and less public credit upon your body. In a rich borough like Paddington there must be numbers of residents who would be glad to have the advantages of the electric light, if it could be supplied to them without the enormous cost of putting down plant to produce it. My right hon. friends, Lord Randolph Churchill and Lord ——, I mean Mr. John Aird, members for the borough, both have this luxury in their homes, and I do not see why 'Reuben' should not have it brought to his door as well. And perhaps some of the parsons may be inclined to get it laid on to their churches and chapels if you begin to distribute it. I imagine it would be a great boon in some of those places. In those churches which are empty it might act as a sort of advertisement, and would be a good 'draw.' But in those which are crowded it would be a boon in preventing them getting so overbearingly hot as a few of them now do. My neighbours and friends, Dr. Clifford and the Rev. Chas. Leach, the ever popular Radical parsons, enjoy the luxury of full conventicles. These July days and August days the soft, cool, clear electric light would be a great blessing both to them and to their people. I have often seen the parson sweltering away trying to make an impression upon the people in a foul and over-heated atmosphere. And more than once I have seen the people boiling away as if they were in a Turkish bath. The new light might help to keep the people awake and the parson cool, and thus give the sermon a chance. I am glad on every ground that you are taking action if only to make inquiry. I shall await report with considerable interest. In the meantime I trust you may enjoy your holidays and keep good tempered.—Your neighbour, REUBEN RUFUS."

A New Electrical Deep Sea Sounding Apparatus.—A party of engineers from London have recently been making a series of experiments in Oban Bay and in Loch Linnhe, for the purpose of testing an electrical apparatus for taking deep sea soundings recently invented by Messrs. Cooper and Wigzell, of London. According to the *Engineer and Iron Trades Advertiser*, Mr. Ogilvie, of Barcaldine, placed his yacht at their disposal, and Councillor Munro accompanied the party to verify the soundings taken from the charts. The apparatus consists of three principal parts connected together electrically by conducting wires. The sounder is a heavy bar about five feet long, having a water-tight cavity at the upper end, which contains special mechanism actuated by the pressure of the water, and at the bottom it is fitted with a grip which, when it strikes the bottom, closes suddenly and secures a specimen, which it brings up. The sounder weighs 26lb. or 40lb., the weight depending upon whether it is required for deep or shallow soundings, and is connected with a strong cast-iron winch, on which the wire is wound, and through which the electrical current passes. This sounding line, which takes the place of the deep sea lead line, is made of galvanised steel wire, and is strong enough to bear a strain of half a ton. Insulated wires connect the winch with the recording instruments, which may be placed in the chart room or any other convenient part of the ship. The indicator of this recording instrument marks the depth as the sounding-bar descends, and becomes stationary at the greatest depth attained by it or on reaching the bottom. Thus it is not necessary to wait until the sounder is wound in again in order to know the depth, and valuable time is saved. The depth recorded is absolutely according to hydrostatic pressure, due to the vertical height of water over the sounder at the time. If there is a swell or high sea running the figures will indicate the depth from the top of the wave in most instances, while soundings can be taken either when the ship is in motion or stopped, a speed of 20 knots an hour making no difference in the results obtained. The experiments tried at Oban Bay were for the purpose of testing some improvements which have just been effected on the apparatus, and the locality was chosen owing to there being, at a convenient distance, some of the deepest water around the British Isles. The results obtained were highly satisfactory, and were found to coincide with the Government charts. The deepest sounding taken, 118 fathoms, was in Loch Linnhe, at the south end of Kerarra.

ALTERNATE-CURRENT ELECTROLYSIS.*

BY MM. J. CHAPPUIS AND G. MANEUVRIER.

The impossibility of producing electrolytic decomposition of sulphate of copper by an alternating current is generally supposed to be an established fact. The absence of all electrolytic phenomena is explained by the assumption that the copper deposited by one current is immediately removed by the other. This negative result is even brought forward as a proof of the exact equality of the two currents. We, however, have been able to justify this explanation by rendering visible the electrolysis of the sulphate, as we have already done in the case of acidulated water.† The experiment is, however, somewhat more complex and more difficult to effect. If a concentrated solution of copper sulphate is placed in a voltameter with platinum electrodes, currents having an average strength of 2·5 amperes (which in the case of acidulated water produce an abundant evolution of explosive gas) give rise in sulphate of copper to nothing more than a considerable heating effect. But if the size of the electrodes is reduced to about 6 sq. mm. (0·1mm. diameter, 20mm. long), there is both evolution of gas and deposition of copper. Electrolysis succeeds equally well with copper electrodes of the same size. As soon as the circuit is closed, a column of minute gas bubbles instantly ascends amidst a cloud of red-brown powdery copper, whilst the electrodes soon assume the appearance of the freshly reduced spongy metal.

Taking all our experiments together, they seem to show that it is possible to establish a sort of equilibrium between the rate of decomposition and the rate of recombination of the constituents of the electrolyte. Once this equilibrium is attained, there seems to be no further electrolysis, properly speaking. Hence, all things which tend to make the rate of the former predominate over that of the latter will cause the reappearance of electrolytic phenomena, whilst those conditions which tend to make the rate of recombination predominant will cause these phenomena to disappear.

Current density is one of the principal things which tend to accelerate electrolysis. It is evident that if on the one hand we increase the quantity of electricity traversing the electrolyte, while on the other we diminish the surface of the electrodes, we shall cause the rate of decomposition to gain on that of recombination, and tend to produce electrolytic action. It is also easy to understand that both electrodes and electrolyte may greatly affect the rate of recombination by virtue of their chemical and physical properties. Hence the tendency to electrolysis depends upon the nature of electrodes and electrolyte, as shown by our previous experiments. Lastly, it can be foreseen that, all things being equal, the rate of alternation will play an important part in these phenomena. For supposing that the rate of alternation becomes so slow that the electrolytic products of one current have time to disappear, either by direct disengagement or by diffusion, before the products of the opposite current appear, it is obvious that no recombination is possible. In this case each current acts like a continuous current of short duration; thus, the slower the rate of alternation the greater the probability of electrolytic effects, all things being equal, and *vice versâ*. We have been able to verify this theory by actual experiment. Employing, as we did, a separately-excited machine, we were able to vary the rate of alternation without affecting the average strength, and, consequently, the average density of the current. We altered the speed of the machine from 1,500 to 2,600 revolutions a minute, thus raising the number of alternations per second from 100 to 173, and by regulating the strength of the current flowing round the field magnets we were able to maintain a constant current. Under these conditions we carried out the two following experiments.

With the machine running at its proper speed of 2,000 revolutions a minute (133 alternations per second), we regulated the strength of the current so as to obtain a state of equilibrium, *i.e.*, a state in which no gas would be evolved in an ordinary water voltameter. We then lowered the speed to 1,500 revolutions (100 alternations a second), and gas was freely evolved at the electrodes. Next with the machine running at 2,000 revolutions and the current regulated so as to produce a remarkable and regular evolution of gas, we increased the speed to 2,600 revolutions (173 alternations a second), and the evolution of gas was immediately arrested. In either case it is possible to counteract the effect of this variation of speed by a proper modification of the current density. Thus, in the first experiment the gases were made to disappear again by increasing the surface of the electrodes; whilst in the second experiment the gas was made to reappear by reducing their surface.

We thus see that speed of alternation and density of current affect the question of electrolysis inversely, so that currents of medium density may give rise to electrolytic effects, provided the alternations are slow enough. It was owing to this that in 1837 de la Rive was able to decompose acidulated water by means of alternate-currents from the then recently invented magneto-electric machines. He was able to get explosive gas on large platinum electrodes of 8 square centimetres surface, so that the difficulty in his case was to get rid of the gases, while in our case the difficulty was to make them appear. This difference arises from the fact that the machine used by de la Rive gave at the most 50 alternations per second, whilst ours gave at least 100 alternations. From these experiments we shall be able to deduce the numerical laws of the several phenomena and the general rules which ought to guide the use of these currents for this purpose.

In a subsequent communication (*Comptes Rendus*, Vol. CVII., No. 2) MM. Chappuis and Maneuvrier give an account of their investigations into the causes of the spontaneous explosions of the mixed gases given off by alternate-current electrolysis, and the means by which they were enabled to avoid this dangerous occurrence. The following is an abstract of this interesting Paper:—

If a voltameter of the ordinary pattern is used in alternate-current electrolysis experiments an explosion inevitably occurs when all the liquid has been nearly expelled from the collecting tubes, and it was only after we had taken special preventive measures that we were able to continue our researches. This phenomena was observed by de la Rive as long ago as the year 1837, and also by Bertin in 1857. De la Rive passed alternate currents from an electro-magnetic machine through an ordinary water voltameter, and noticed that the platinum electrodes became coated with a powdery platinum film, and that if they were then introduced into a vessel containing explosive gases an explosion resulted. From this de la Rive concluded that the phenomenon was due to the so-called catalytic action. Bertin decomposed acidulated water by a continuous current from a battery of 50 Bunsen cells, and collected the evolved gases in the same receiver. He observed that the gases exploded as soon as the receiver became nearly full, both when platinum was used for either electrode and when platinum was used as the positive and iron as the negative electrode. With platinum and copper, or with platinum as the negative and some oxydisible metal as the positive electrode, no explosion took place. Bertin attributed the phenomenon neither to catalysis nor heating, but to the "polarisation of the electrodes" [an explanation which seems to leave a good deal to be explained]. Neither of these theories suffices to account for the facts as observed by us. Like de la Rive we observed the black film, but it has nothing to do with the detonation of the gases, since this often takes place long before the appearance of the film and when using perfectly new electrodes. Like Bertin, we produced explosions with other metals than platinum; but, unlike him, we came to the conclusion that polarisation had nothing whatever to do with the phenomenon. For take a new electrode and fill a bell-glass with the mixed gases, then substitute another new electrode; the gases explode the moment the current is put on, provided only that the electrode is sufficiently well out of the water. We attribute these explosions to the electrodes becoming incandescent by reason of their progressive emersion from the liquid, increasing as it does the current density and the resistance, and diminishing the cooling effect due to contact with the solution. We have been able to make this incandescence actually visible.

We take electrodes of platinum, which are placed in a bent tube. One end of the platinum is soldered to the copper wire conveying the current, the other end is soldered to the glass. We have noticed that the end soldered to the glass becomes incandescent at the moment of detonation. One of the electrodes having been broken, an almost invisible point projected out of the glass, and the moment the current was started this projection became incandescent, exploding the gas bubbles as soon as they

* Translation of a Paper by MM. J. Chappuis and G. Maneuvrier, read before the Académie des Sciences. (*Comptes Rendus*, Vol. CVII., No. 1.)

† See *The Electrician*, 29th June, p. 237.

Digitized by Google

came in contact with it. Again, if only the tips of the electrodes are allowed to dip into the liquid, incandescence and detonation are the immediate result.

It follows from this that all circumstances which tend to increase the heating effect, such as increase of current density and diminution of electrode surface, tend to accelerate explosion. Thus, with a ·5mm. wire, detonation did not occur until the gas had pushed down the liquid to within 5mm. of the end of the electrode. On the other hand, with a 2mm wire, the explosion took place when the liquid was still 25mm. from the end. To prevent explosion we keep the electrodes always well immersed in the solution by enclosing them in a conical or cylindrical funnel, at the top of which there is a small straight tube, which carries off the gases to a receiving vessel. This, or any other similar arrangement, is well adapted to obviate all danger in the manipulation of the explosive gases given off in alternate-current electrolysis.

WHEATSTONE AND STROH'S SUBMARINE CABLE KEY FOR MORSE SIGNALS.

In connection with the article which appeared in this journal on June 29th, p. 242, under the title of "Delany's Improvements in Submarine Cable Telegraphy," the following extract, taken from a patent issued to C. Wheatstone and J. A. Stroh in the year 1870, is of considerable interest. On comparing the two descriptions it is impossible to doubt that they are substantially identical:—

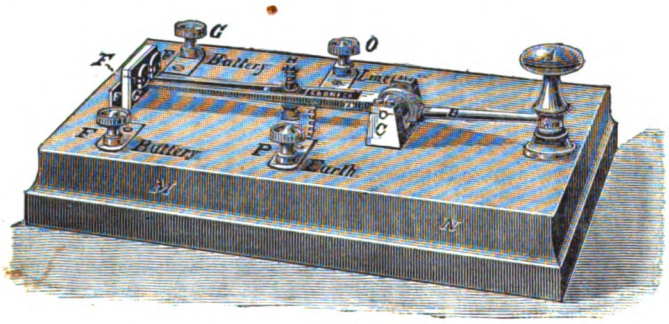

Fig. 1.

"*Simple Reversing Key.*—Our fourth improvement is a method of constructing a manipulating key for directing into the telegraphic circuit alternately inverted currents from a voltaic battery, which last only during the upward and downward motions of the lever; the separation of the battery from the line and the connection of the latter with earth being effected when the lever reaches the two limits of its motion.

"On the insulated stand, M, N (Fig. 1), is mounted the manipulating lever A, B, with its bearing at C. Upon the back of the lever are prolongations formed by two metallic blades D and E, which are permanently in connection through spiral wires—one with line through the binding screw O, the other with earth through the screw P. The extreme ends of these blades press against the sides of small curved blocks of ebonite, so shaped that when the key is depressed the blades ascend on the right-hand sides, and when it is elevated they descend on the left-hand sides of the blocks. On each side of each of these curved blocks is inserted a small piece of metal flush with the side face of the ebonite, against which the metallic blades rub and make contact in their passage up or down. The two pieces of metal which face each other on the inner sides of the curved blocks are connected to the zinc pole of the battery through the binding screw G. The two metallic contact pieces on the outer sides of the blocks are permanently connected with the copper pole through the binding screw F. By this arrangement when the key is depressed a current is sent into the line in one direction, and while it is being released a current in the opposite direction is transmitted. Between the terminal screws O and P is a vertical metallic pillar, H, provided with flanges with which the blades D and E make contact at their extreme points of elevation or depression, so that during each ascent or descent before the extreme ends of the blades leave the ebonite blocks they are put into contact with each other, and the line put for an instant into contact with the earth and discharged.

"*Reversing Key with Fly.*—Our fifth improvement consists of an inverting key by which the battery is cut off the moment after its inversion, enabling currents of equal duration to be transmitted into the line independently both of the time the key is allowed to rest at either of its limits and of the rate at which it is moved.

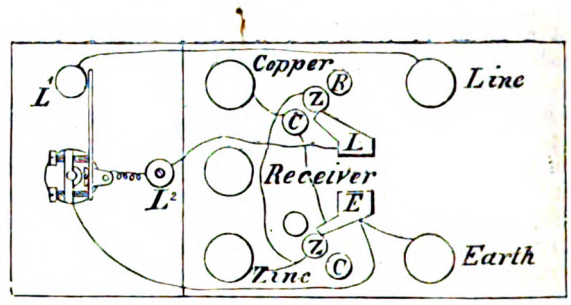

Fig. 3.

"The first part of the instrument consists of an inverting key, which may be of the ordinary construction, and is provided with the usual commutating contacts for inverting the battery between the earth and line terminals. The second part of the instrument consists of a mechanical interruptor, which is inserted in the line circuit, and whose velocity of motion determines the duration of the current sent by the key. The inverting key is shown in perspective in Fig. 2, and a diagrammatic view of the connections in Fig. 3. It consists of a lever K, K, provided at the back with a spring prolongation A upon which on opposite sides are fixed two metallic blades E and L, the former being permanently connected through the spiral wire E^1 with earth, the latter being permanently connected through the spiral wire L^1 with the mechanical interruptor, and thence with the line terminal. The metallic blades play between

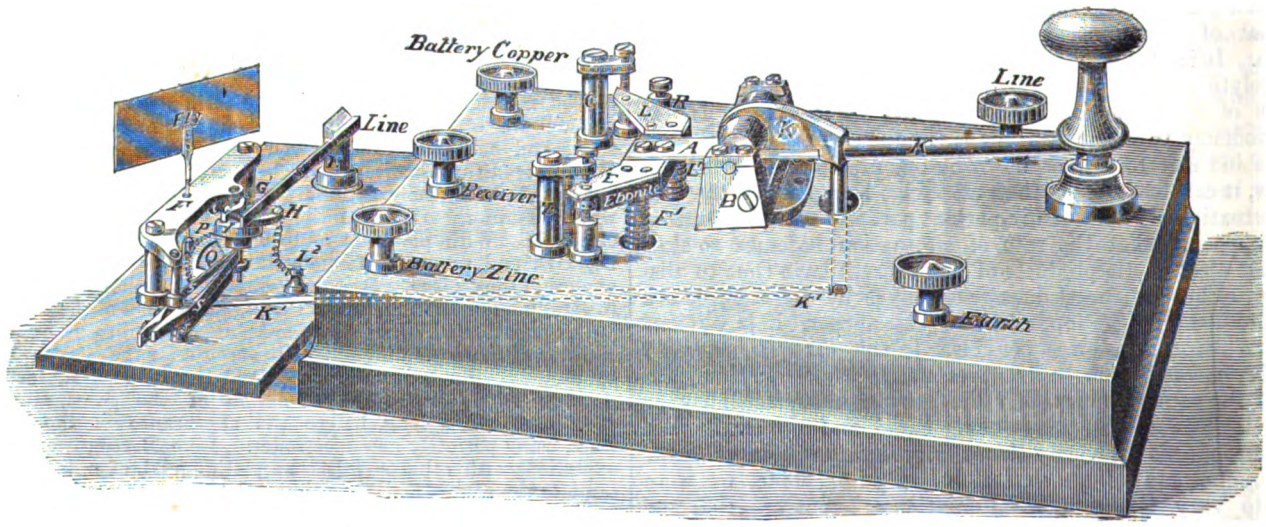

Fig. 2.

Digitized by Google

four contact anvils upon the pillars Z and C and the studs z and c. The pillar C and stud c are connected with the copper pole of the battery, whilst the pillar Z and stud z are connected with the zinc pole. Thus when the blades are elevated against C and Z, zinc is to earth and copper to line; whereas when the key is in its position of rest, as shown in the drawing, copper is to earth and zinc to line. This portion of the apparatus, therefore, forms a double current or reversing key, which may also be of the usual construction.

"The second part of the instrument is connected with the key by a rod, K^1, attached to the vertical prolongation of the lever K. This rod, K^1, is coupled to an arm, J, attached rigidly to a vertical arbor pivoted in a suitable frame, F. Attached to a collar on this arbor are two adjustable parallel blade springs, s, s^1, the further ends of which embrace two pins, one upon the arm J, and the other upon one side of the oscillating system G H I. This oscillating system is carried upon a vertical arbor, upon the lower part of which the quadrant (Q) of a spur wheel engages with a pinion, P, the shaft of which carries a fly above it. Half-way up is a block of ebonite, I, carrying a small triangular metal slab, H, in connection with the blade L of the key, through the spiral wire and screw L_2. At the top of the oscillating arbor is a small cross with two contact screws, G, G^1, both of which are to earth through the arbor and frame. The slab H is provided with a vertical pin, which, when the system oscillates, rubs against the face of a spring, s^{11}, which is connected electrically with the line terminal of the key. The line circuit between the blade L and the line terminal is therefore made and interrupted between the pin on H and the spring s^{11}. When the key is at rest the rod K^1 draws the arm J forwards, and keeps the left-hand spring s pressed against the pin upon the quadrant Q; the oscillating system is therefore held at rest, as is shown in the drawing, the line spring s^{11} being pressed from contact with the pin upon H by the front contact screw G, and the line is therefore to earth. When the knob D of the key is depressed, the blades E and L being raised to the upper anvils C and Z, the direction of the current is reversed. At the same time the rod K^1 is thrust back, causing the right-hand spring s^1 to press against the pin upon the quadrant Q and make the system rotate as fast as the fly will allow it to. In rotating, the screw G (earth) leaves the spring s^{11}, which falls for an instant upon the pin upon H, thereby completing the line circuit with L_2 and L and allowing a current to pass into the line. This is, however, immediately afterwards interrupted again by the further screw G^1, which as it comes round forces the spring s^{11} from the contact pin. When the key is released again the rod K^1 pulls the spring s against the pin of the oscillating system, causing the quadrant and fly to rotate in the opposite direction, and the current (inverted by the blades L and E) to be transmitted in the opposite direction for an instant as the contact pin of H passes by the spring s^{11}. When the key is not in use for transmitting signals it is placed in its position for receiving. For this purpose the metal block B carrying the bearings of the lever K is made turnable about a vertical pin. When receiving, therefore, the knob of the lever is drawn towards the left by which the blade L is brought to rest upon a stud, R, connected with the receiving instrument. The horizontal movement of the lever also has the effect of relieving the tension of both the springs s, s^1, of the interruptor, so as to allow the oscillating system to assume a central position, and the pin upon H to rest in contact with the line spring s^{11}. Currents therefore arriving at the station pass from the line terminal over s^{11}, pin on H, L_2, spiral wire L_1, blade L, and stud R to the receiving instrument."

REVIEWS.

Phenomenes Electrique de l'Atmosphere. By GASTON PLANTÉ. (Paris: Baillière et Fils, 1888.)

The present year of grace is likely to be long remembered for the abnormal frequency of thunderstorms and other atmospherical disturbances. It may also be distinguished as the year in which two valuable memoirs, dealing more or less directly with the *experimental* investigation of electric meteorology, have seen the light. The lectures of Dr. Oliver Lodge have quite recently been reprinted in this journal; and we have now before us a volume by M. Gaston Planté, containing an account of researches in the same direction. The book covers, however, wider ground than that recently taken up by Dr. Lodge, and amidst much that is new and valuable we find a good deal which has already been published by the author in his earlier memoirs; some things also we find to which we are unable to yield entire assent.

The author is of opinion that the origin of atmospheric electricity is to be found not in any meteorological process, but in "a primitive charge of positive sign, belonging to the earth as a whole," and which is undergoing a very gradual secular diminution. As all our measurements of potential are relative, there can be nothing intrinsically improbable in this assumption. In place of seeking for a constant source of generation to account for the observed differences of potential between the surface of the earth and the regions of the atmosphere, we should have to explain the causes of the varying distribution of electrical density. It would seem worth while to pursue the suggestion beyond the point where M. Planté leaves it.

The chief interest of the work does not, however, lie in the theorising, but in the numerous and ingenious experiments by which M. Planté has sought to reproduce, upon the scale of the laboratory, the electrical phenomena of the heavens. Whether the analogy between the experimental and the natural phenomena is in every case as close as the author supposes is open to question, but it is at least certain that we have here described a series of brilliant and striking experiments which will be to most of our readers as novel as they are interesting.

Most of these experiments were carried out by means of M. Planté's great secondary battery, which now consists of 1,600 cells, giving him, therefore, the command of nearly 4,000 volts. Unfortunately, the author has not thought it necessary to give any measurements of current or resistance. We read of 400, 800, and 1,600 cells, discharged "in quantity" or "in tension," but we have no clue as to the current or the energy actually employed in any case. In some cases the "rheostatic machine" is used.

We shall proceed to quote some of these experiments, beginning with a simple case, in which the analogy appears to be successfully established. The phenomenon in question has only once been observed in nature, probably because the necessary conditions are not often present. This is a case in which a lightning conductor had an earth connection carried underground and terminating in the middle of a pond. The conductor was seen to receive a flash, and at the same moment a jet of water spurted into the air from the midst of the pond. By means of a powerful static discharge taken into a basin of water this is easily imitated, and is very likely due to a sudden generation of steam at the end of the conductor.

A well-authenticated case occurred in Germany in 1884, in which a flash of lightning struck a building and appeared to make its exit through a window, leaving a jagged hole in the glass. The next instant a powerful jet of water rose from the soil, came straight through the same hole, and struck against the ceiling of the room, almost deluging the house. This case seems more difficult to account for than that last mentioned; and it is, perhaps, a little doubtful whether the experiment offered by M. Planté is quite analogous. A fine wire is passed through a glass tube of small diameter, and an inch or so at the end is allowed to dip into a basin of salt water. A current "of high tension" sent through the circuit thus formed causes the water to rise in the tube to the height of 25 or 30cm. The upper surface of the water becomes luminous, and gives off jets of steam. The experiment is in any case a pretty one.

These, however, are instances of rare and, so to speak, accidental phenomena, and the investigation of the more regular electrical manifestations is even more interesting. In order to imitate the fall of hail, M. Planté has devised a very ingenious experiment. A saturated solution of potassium nitrate, or other suitable salt, is placed in a shallow vessel, into which dips an electrode connected with a secondary battery of 400 cells. The extremity of the conductor connected to the other end of the battery is wrapped round with moistened paper, so as to present a considerable surface. When the conductor so prepared touches the surface of the liquid an extraordinary effect occurs. An arc of the so-called "semi-incandescent" type is formed, jets of steam spurt from the surface, and at the same time large drops are projected into the air in all directions. Since these drops consist of a saturated solution they solidify as they fall, producing a "hail" of saltpetre. M. Planté concedes the difficulty of finding an atmospheric analogy for the

Digitized by Google

saturated liquid, but, if we understand him aright, he suggests that if an electric discharge takes place amongst cirrus clouds floating—as is frequently the case—at such heights that their particles consist of very minute ice crystals, then the following series of results ensue:—First, the heat developed by this or by an immediately preceding discharge liquefies the ice particles; next, the resulting liquid is scattered in large drops, as in the experiment shown; and lastly, the drops are again congealed as they fall, and so reach the surface of the earth in the form of hail. Without offering any opinion as to the exact degree of analogy here presented, we would remark that the origin of hail has long been a *crux* to the meteorologists, and the suggested explanation should not be dismissed merely because it is somewhat complex.

The remarkable phenomenon known as "globular" or "ball" lightning has long been a favourite subject with M. Planté, and in an appendix at the end of this work he collects quite a large number of well-authenticated instances. The attention of the scientific world was first drawn to the subject by Arago, in the year 1838. The descent of globes of fire from the clouds had long been a popular belief, but the "thunderbolt" superstition with which it appeared to be intimately associated had tended to discredit the facts in scientific circles. The existence of the phenomenon is now, however, perfectly well established, and certainly admits of no doubt in the mind of the present writer, who has himself been privileged to witness a display of this character at rather uncomfortably close quarters. This instance has already been related in *The Electrician*,* and the general impression left on the writer's mind is closely in accord with many of the stories related by M. Planté. In the case alluded to, a fiery globe, coming apparently from the fire-place, moved with a gentle undulating motion around the room, finally disappearing, without explosion, by the way it came. M. Planté speaks of this slow, wavy motion as characteristic, and he also gives more than one instance in which the ball passed up the chimney of a dwelling-house. In *The Electrician* of Sept. 3, 1886, p. 333, a case is recorded which is similar in this detail; but the globe coming in contact with the body of a man killed him on the spot, although without detonation. Arago notices that some balls disappear with and others without explosion. Planté records instances in which the ball was of an ovoid shape, and others in which it seemed to rotate with great rapidity. In one case, where the aperture of a disused stove pipe had been covered by wall paper, the ball tore away the paper, and disappeared up the pipe. In the earliest case quoted by M. Planté, which occurred at Stralsund in 1670, the apparition of a single ball was accompanied by a succession of detonations. He also quotes from this journal an account of a "beaded" flash which broke up into a great number of fire balls. This occurred at Westminster during the great storm of August 16th last year.

M. Planté has carried out a great many experiments in order to imitate these phenomena. An arc discharge taking place between a metallic electrode and a basin of distilled water, with 4,000 volts in circuit, takes the form of a globe of fire when the arc is extended to its greatest limit, and by causing the electrode to swing to and fro over the surface M. Planté gets an effect which, in the dark, closely resembles in appearance the globe discharge. But it is scarcely possible that these phenomena are really identical. In the *Comptes Rendus* of 19th August, 1878, the author published the description of an experiment with a plate of mica formed into a condenser by coating each side with tinfoil. When charged up to about 2,000 volts, the mica gives way at the weakest part, and a little detached globule of incandescent tin starting at this point makes its way by an irregular or sinuous course all over the surface of the plate, cutting a narrow groove or trace in the mica. In 1877 M. Planté improved upon this by using an air condenser in which the metallic plates were covered with paper and moistened with distilled water; an E.M.F. of 4,000 volts was used in this case, and the wandering globule consisted of water vapour, air, and hydrogen.

It is worth while to mention here an experiment originally due to Mr. T. Blakesley (M. Planté attributes it, in a footnote, to M. C. Moussette, by whom it was no doubt independently discovered). If a photographic dry plate after development be placed between the poles of a Holtz or Wimshurst machine, an E.M.F. insufficient to strike across the plate will start a wandering spark, which moves irregularly to and fro upon the surface.

M. Planté's experiment with the moistened coatings is perhaps as near an approach as can be made to the actual meteorological conditions. In order to apply this to the explanation of the natural phenomena he assumes that between the thundercloud and the earth there is formed "a column or funnel of damp air strongly electrified, visible or invisible, which serves as an electrode, through which a continuous discharge takes place, manifesting itself at the lower extremity as a ball of fire."

The limit of our space will not allow us to quote the interesting series of experiments by which M. Planté endeavours to support this explanation. For our own part we are unable to feel that the phenomenon has yet been elucidated to a thoroughly satisfactory extent, although the beauty and originality of M. Planté's work none the less deserves the fullest recognition. We have left ourselves no room to speak of the miniature cyclones, water-spouts, and auroras which M. Planté has produced in his laboratory; but we may, perhaps, return to this part of the subject on a future occasion.

* See *The Electrician*, August 20th, 1886, p. 294.

"Electro-plating." 2nd Edition. By J. W. URQUHART. (Crosby Lockwood and Son, London, 1888.)

This book has a great excellency and a great defect; it is simply and clearly written, but it is deficient in the scientific foundation of the subject. In nearly all the details of the art it is very explicit.

In the preface, the author states "that without much rule of thumb any ordinarily intelligent man may become an expert in electro-deposition with a very little science indeed." This appears to us to be a very misleading statement, because a man can only become an expert in electro-plating, either by means of "rule of thumb" experience, or by means of scientific knowledge; if he is without either he must fail. There is no short-cut or royal road to excellence in electro-plating, any more than in any other pursuit; and a combination of scientific knowledge and "rule of thumb" is, in our opinion, the most certain means of success. It is further stated in the preface:—"This work has been prepared for the benefit of that numerous portion of the community who have not the advantage of books, and who could with difficulty understand them if they had." And on page 7 the author says, "that this treatise is written for those who know nothing of chemical or electrical science," and "the reader is assured that the practice of electro-deposition may be carried on with only a modicum of scientific knowledge." It is rarely the case that a thoroughly informed author of a scientific book speaks in favour of "a modicum of scientific knowledge" relating to his subject. On p. 62, the writer remarks that "the worker himself cannot be expected to be a trained chemist or electrician, and give, as he does, his services for a small wage weekly." This statement is reasonable; but there is a very wide difference between "a trained chemist or electrician" and a man "who knows nothing of chemical or electrical science," and is therefore ignorant of the fundamental principles which govern his work. As the author assures the reader "that the practice of electro-deposition may be carried on with only a modicum of scientific knowledge," we are not surprised to find a deficiency of such knowledge and of preparatory chemical and electrolytic information in his book. From this deficiency of scientific principles, and from the above statements and others in his book, we conclude that the author considers such knowledge to be of a kind which may be omitted both by the teacher and learner. He, however, admits, on p. 37, that "a knowledge of the subject of electrolysis would prevent a great many failures."

Plainly speaking, the book appears to be intended to enable a man to work successfully at electro-plating "with a very

Digitized by Google

little science indeed." This is exceedingly plausible and tempting to an uneducated workman possessing but little money, and it may induce him to buy the book; but we consider it to be false economy, very risky, and generally disastrous. For his own self-improvement, and for his ultimate success, irrespective of an immediate and direct increase of wages, we would recommend the workman not to be satisfied with "a modicum of scientific knowledge" relating to his employment, but to continually add to his stock of information respecting it, and certainly to learn the fundamental principles, and acquire the preparatory knowledge which illuminate his entire working.

As an example of the effect of carrying on the practice of electro-deposition "with a very little science indeed," we find on page 118, in both editions of the book, instructions given for making the double sulphite of sodium and silver-plating solution, by passing "sulphuretted hydrogen (*see* process, p. 44)," made "from sulphide of iron with diluted sulphuric acid," through a solution of washing soda until the solution is neutral, and then adding a saturated solution of silver nitrate, "as long as the solution re-dissolves the silver" precipitate. No one possessing even a modicum of chemical knowledge would attempt to use "sulphuretted hydrogen gas" for such a purpose—first, because it would not produce the substance wanted, but quite a different one, viz., sulphide of silver; and second, because it would not re-dissolve the sulphide of silver precipitate. The solution mentioned is prepared, not with "sulphuretted hydrogen," but with sulphurous anhydride gas, and the way to make the latter is not described in either edition of the book. A very moderate amount of preparatory chemical knowledge would have prevented the author from giving these erroneous instructions. It is only fair to say that we have observed no other serious error in the book. Notwithstanding its fundamental deficiencies, however, the book is full of details of useful instructions in electro-plating, described in the simplest language, and it will prove of great service to ordinary electro-platers, especially to those who have acquired suitable preparatory knowledge of the principles of chemical and electrical science.

Short Lectures to Electrical Artisans; being a Course of Experimental Lectures Delivered to a Practical Audience. By J. A. Fleming, M.A., D.Sc. (Lond.) Second Edition. (E. and F. N. Spon, London, 1888.)

We think it a matter for considerable satisfaction that a second edition of these Short Lectures has already been demanded. This book is one which we shall hope to see run through many more editions yet. There are many persons not strictly belonging to the artisan class who would derive much advantage from the study of this work. We are frequently asked to recommend suitable books to people who possess some general knowledge of electricity, but who wish to obtain a firmer grasp of the principles of electrical engineering. This is one of the books which in such cases we most strongly recommend.

ON THE ELECTRIFICATION OF METAL PLATES BY IRRADIATION WITH ELECTRICAL LIGHT.

The July number of the *Phil. Mag.* contains the following translation of a Paper, by William Hallwachs, which originally appeared in the *Göttinger Nachrichten*:—At the close of an article recently published in Wiedemann's *Annalen*, Vol. XXXIII., p. 301, I had mentioned that, to judge from preliminary experiments, metal plates become electrostatically charged when irradiated with the electrical light. It could be seen from the outset that we were not dealing here with charges at potentials that could be measured by a gold-leaf electroscope. In order to ascertain whether a charge measurable with sensitive electrometers could not be obtained, the final experiments were made as follows:—The circular metal plate, 8 centim. in diameter, to be illuminated was suspended by an insulated wire in the centre of a cylindrical sheet-iron vessel, 50 centim. in length and 37 centim. in diameter, which lay with its axis horizontal. The surface of the metal plate was coated with rust, but one portion of the surface was brightly polished and was put to earth. The wire by which the plate was suspended passed through, but insulated from, an earth-connected brass tube, to a Hankel's electrometer, which was chosen for these experiments on account of its small capacity. In the lid of the metal cylinder was a circular aperture of about 8 centim. diameter, which transmitted the rays of the arc lamp to the plate hanging inside. This aperture was covered by a piece of wire gauze, in order to prevent any appreciable induction of the lamp on the plate to be irradiated, without excluding the action of the luminous rays on it. From former experiments (loc. cit., p. 305) this latter phenomenon was to be expected, and was confirmed by the present experiments. The luminous arc was at a distance of 45 centim. from the plate, the rays coming from it passed through a diaphragm 6 centim. in diameter before entering the metal case. The case was of rusty iron, so that the contact potential against the plates to be suspended was always negative. In this case only could the rises of potential indicated by the electrometer be indubitably explained. For if the plate had been negative to the case, a rise of potential would have occurred due to the transport of negative electricity by the illumination. If the plate, however, was positive towards the case, and therefore possessed a positive charge, an increase of potential could only be due to the fact that positive electricity was produced on the plate by irradiation. The determination of a difference of potential due to contact by a method formerly described in Wiedemann's *Annalen*, Vol. XXIX., p. 7 (1886), gave for rusty iron towards brightly-polished zinc 1·2 volt. If, now, the aperture in the diaphragm through which the rays of light could fall on the plate was closed by a mica plate, the electrometer was at rest when the arc was produced. When the mica was replaced by a far thicker plate of selenite, the galvanometer gave a gradually increasing deflection indicating positive electricity. This at once ceased to increase when the mica again replaced the selenite. The rise of potential cannot therefore be due to an inductive action, nor can it be referred to the action of heat. The complete absorption of the action by mica, and the great transmissibility of selenite are here as prominent as in the action of light on electrostatically charged bodies, so that the excitation of electricity is probaby due to the same rays as that phenomenon. The metals which have been used for the experiments just described were zinc, brass, and aluminium. In all three positive electricity occurred on irradiation with brightly-polished surfaces. Old surfaces no longer show the phenomenon. The radiation itself lowers the potential to which the plates can be electrified, so that with any succeeding experiment made with the same surface the potential obtained is lower, while the rise to it takes place more rapidly, and the decrease is greater than when for the same interval of time between the experiments the plate was not illumined. The maximum potential with zinc amounts to over a volt, with brass to about 1 volt, and with aluminium to 0·5 volt. These values are the highest which have as yet been obtained, as the maximum values change with the condition of the surface. As I have had to interrupt these experiments I have ventured meanwhile to communicate the chief results. Whether the excitation of electricity by radiation with electric light is in direct connection with the loss of electricity by electrostatically-charged bodies when irradiated I cannot state, as it has hitherto been impossible for me to make any experiments in this direction.

BOOKS, &c., RECEIVED.

"Über Molekularphysik." By F. Lindemann. Separate Impression from the *Transactions* of the Physico-Economic Society of Königsberg.

The Electrician.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial and Publishing Offices
No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.
Telephone No. 2714.

All Communications to be addressed to "The Electrician," 1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to "The Electrician."

All letters intended for insertion in "The Electrician," or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.

"The Electrician" is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.

"The Electrician" is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained at all Booksellers and Newsvendors; or direct from the office as above.

SPECIAL NOTICE.

Owing to the increase in the number of pages of "The Electrician," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months.
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	... 12 6	... 24 0
„ Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	... 14 6	... 28 0
The rates for the United Kingdom remain as follows:—	5 0	... 10 0	... 19 6

TO ADVERTISERS.

"The Electrician" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to this office.

Advertisements intended for the current issue must be handed in not later than 4 p.m. on Thursday.

TECHNICAL PRINTING.

"The Electrician" Printing and Publishing Company (Limited) *beg to inform Electricians and Electric Light Engineers that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

The Electricians' Directory.

Royal 8vo. Cloth Boards, 3s. 6d. Boards, 3s.

At the end of December in each year is issued The Electricians' Directory and Handbook. *The* Directory *was established in 1883, and has now attained considerable proportions. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, accompanied in many cases by Portraits.*

THE DIRECTORY FOR 1889 IS IN PREPARATION.

"THE ELECTRICIAN" IN THE UNITED STATES.

Similarly, "The Electrician" *can be obtained in America at the Offices of* "The Electrical World," *168 to 177, Potter-building, New York.*

"The Electrician" *can also be obtained from* **D. Van Nostrand, 23, Murray-street, and 27, Warren-street, New York.**

The Rate of Subscription for American Subscribers (payable in advance) is $6 per annum.

THE ATLANTIC CABLE RATES.

We are glad to be able to announce this week that the war of rates between the several Atlantic Telegraph Cable Companies has virtually ceased, and that on the first of next month the charge by any of their lines will be a uniform one of 1s. per word. It is curious to note that, according to the statement of the Chairman of one of the English companies, the American companies, which were primarily responsible for the destructive rates prevailing since May, 1886, are now quite ready, and even anxious, to place them on a friendly and more profitable footing. Only one company, the French Atlantic, held back from the rest until the last moment; but after a show of resistance, and a consultation with the French Government, this company also has given in its adhesion, and there is now a combination of the five companies to work their cables henceforth at a rate which, while it may not be too low to yield

Digitized by Google

a reasonable profit to them all, will not be so high as to invite any new competitor. The parties to this prolonged dispute have, in fact, arrived at the conclusion that the experiment of competition has been sufficiently exhaustive, not to say exhausting, and that it has furnished them with trustworthy data on which alone they can base a commercially sound tariff of charges.

The history of the conflict, not less than the outcome of it, in its bearings upon the commercial aspect of submarine telegraphy, may be usefully studied at the present moment. More than two years ago the English companies, owing to the laying of a new and quite superfluous cable from the other side of the Atlantic, were compelled to reduce their word-rate from 2s. to 6d. We say compelled, because the intruding cable started with a rate of 1s. 8d., and unless the existing companies were content to acquiesce in this reduction—in other words, to condone the competition—they were bound to retaliate by reducing their own rates to a much lower figure. With some advantages on its side the Commercial Company then reduced its rate to 1s., while the other four companies were running at sixpence; but it was obvious from the first that this state of affairs could not last, and in the autumn of 1887 the Commercial Company reduced its rates to the level of the rest. Eighteen months' trial of an artificial rate was evidently not a success, and since last September the whole of the cables have been working at a uniform rate of sixpence a word. By that time, however, it had become plain that the sixpenny rate could not pay any of the companies; and, if possible, this fact became plainer when the new company entered into competition on equal terms. From that moment the sixpenny tariff was doomed, for if a shilling tariff would not pay, worked independently, certainly a sixpenny tariff would not. It did not, apparently, take long to convince the proprietors that competition, except on purely philanthropic lines, was no longer practicable, and that an amicable alliance with the other cables was the only basis on which its own could ever hope to earn a fair profit.

This stage being arrived at, the next step necessary was the fixing of a tariff on which all the parties would be willing to work. One or two of the companies wished to return to the 1s. 8d. rate of 1886; but this has been overruled, and we think wisely. The sixpenny rate, although in itself unprofitable, has greatly developed the traffic, both in area and in bulk; and whatever may come of the increased rate now adopted, the ground on which it will begin is far superior to that on which the higher tariff was worked three years ago. The English companies believe that there will be no serious falling off in business under the increased rate; but, be that as it may, the maintenance of the sixpenny rate for two years and three months has made the experiment of a shilling rate a possibility which otherwise probably would not have been entertained.

On this result at least the public are to be congratulated. They have enjoyed for a considerable period the advantage of a very low tariff, and are now to have a tariff much lower than it would have been but for that advantage. Some of the companies' shareholders urged the adoption of the 1s. 8d., or even a 2s. rate; and, in view of the losses they have sustained, they were entitled to make this demand. But at present it is wiser to be content with the directors' proposal, or at all events to give it a fair trial. What the companies have now to do is to work for profit, not for each other's destruction; secondly, to provide themselves with an adequate reserve fund; and lastly, to prevent the possibility of any fresh competition arising.

The companies themselves, as well as the public, have reason to be satisfied with the prospects now before them. Not only have they worked up an immense field for telegraphic business, but they have disarmed the hostility of their customers. The 6d. tariff has been borne patiently and tested to the uttermost that could be reasonably expected. The diminished dividends have spoken eloquently even to a public not over inquisitive as to profits so long as prices rule low; and the result has been, so far, that no outcry has been heard against a rise in prices which a few years ago would have been hailed with a storm of indignation. Only in one quarter have we noticed a mild protest on the ground, apparently, that as the traffic has increased 140 per cent. under the 6d. tariff, therefore it ought to be remunerative. But the fact that it is not remunerative is not disputed, and, on the whole, is accepted as a justifiable reason for increasing it. The decrease in the rate was in much greater proportion; and, as the phenomenon of working expenses increasing considerably with augmented traffic has lately been demonstrated in the Postal Telegraph Service of this country, the general public are prepared to view the situation with unaccustomed reasonableness. Of course there is the usual talk about the hundreds of thousands of people on both sides of the Atlantic panting to send cablegrams to each other, and waiting only for the rates to be lowered; but it is not likely the *Daily Telegraph* will succeed in this line of argument where Mr. Henniker Heaton has failed. It may be true, and we hope it is, that "Transatlantic telegraphy is at present, as regards bulk, nearly in its infancy;" but as it brings us no nearer finding capital to provide the full-grown child with more cables, the proposition does not call for serious discussion. Similarly, except as a sample of popular misconception, we need not give greater publicity to the speculation that Mr. Edison's "perfected phonograph" may "aid in recovering the lost sixpenny tariff." Whatever its inventor may expect, or the *Daily Telegraph* may predict of it, the phonograph has at present about as much relation to submarine telegraphy as the sewing-machine has to steam locomotion. Just now, therefore, we have only to deal with the facts as they are; and among several foolish things in the article from which we have just quoted there is one passage of sense and reason on which the Atlantic cable companies might rest their whole case, namely, that private enterprise is not expected to make sacrifices out of revenue in order to "do good" to the public.

THE SPRAGUE ELECTRIC TRAMWAY AT RICHMOND, VIRGINIA.

Under the title of "The Solution of the Municipal Transit Problem," a Paper which has attracted much attention in the United States was read on June 17th, before the American Institute of Engineers, by Mr. F. J. Sprague. The Paper is of very considerable length, and deals in the first place with the general question of the tramway service in large cities, and proves from authentic statistics that while the working cost of the cable system of traction is from 50 to 70 per cent. that of horses, the cost of the electric system does not exceed 40 per cent. After giving numerous details relating to the running of the Sprague motors, the author describes the difficult character of the street lines in Richmond, where gradients of 1 in 10, and curves of 27ft., 30ft. and 40ft. radius are frequent. He then proceeds as follows:—

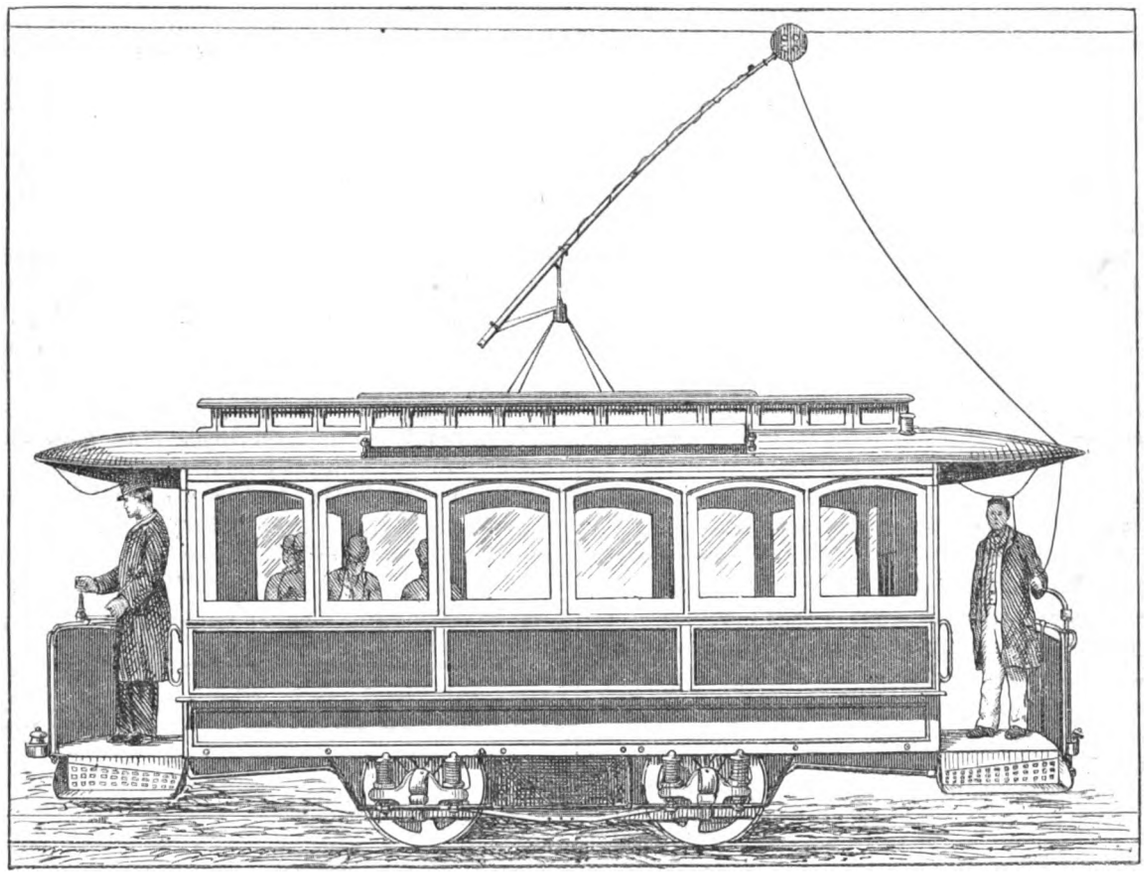
The power house is situated two blocks away from the nearest point of the line, and is almost equi-distant from its extremities. As a distributing point, it is, therefore, both theoretically and practically, a central station. In the construction no expense has been spared, and the performance of the station has justified it. The battery consists of three cylindrical return tubular boilers of the latest pattern, mounted on a Jarvis patent furnace, their capacity being 125 horse-power each. The water is taken from the city mains or from a well. All feed-water connections are of brass pipe. From the pumps the water passes first through the feed-water heater, where it is heated to from 150 to 200 degrees Fah. From there it goes to the filter. The draft in the furnaces is regulated by an automatic steam damper regulator, which, with anything like regular firing, keeps a pressure within two pounds of that for which the regulator is set.

Digitized by Google

The boilers all feed into one main feed steam pipe, which in turn leads to a separator, a large iron cylinder into which the steam passes, the water falling to the bottom and the dry steam being carried off at the top. All live steam pipes in the boiler room are covered with magnesia.

The present battery occupies less than half the available space in the boiler room, so that four more boilers can easily be put up when it becomes necessary to enlarge the plant. Two more have just been added. An important feature of these boilers, which are the source of power of the whole system, should not be overlooked—that is, the quantity of coal burned. Where a very perfect combustion is obtained a grade of coal can be used which would be impracticable in an ordinary furnace; the mixture at present being used is two parts screenings to one part bituminous, costing from 1·75dol. to 2dols. per ton delivered. As the station is only three hundred feet distant from the depots of three railroads, coal can be obtained almost at the door. From the boiler room, both the steam and exhaust pipes run in an underground, mineral wool-packed trench to the engine room.

The railroad engines, of which there are at present three, are of the Armington and Sims high-speed type, and develop when running at full load 125 horse-power each at 250 revolutions.



The Sprague Electric Tramway at Richmond, U.S.A.

Each engine drives two special Edison dynamos of 40,000 watts capacity each, wound for 500 volts maximum pressure. The dynamos feed into copper "bus" bars, supported on the walls by porcelain insulators.

Each machine has its independent ampere meter, and in addition there is a general ampere meter at the end of the positive "bus" bar. From this bar the current passes to four snap switches, each switch being connected through a three-plug safety switch-block to one of the feeders supplying current to the main-line wire. These four-feeder wires tap into the line wire at different points, thus maintaining the pressure approximately equal all along the line. At the ends of one of the feeders in the central station pressure indicators are to be attached which will indicate the voltage at the junction of one of these feeders with the main-current wire, and this will serve as a guide.

The electric circuit consists of two parts—the overhead and the ground circuit, each being of compound character. Along the kerb stones, at distances of 135ft., are 30ft. poles, inserted into the ground at a distance of 5ft. Great difficulty was experienced at first on account of the clayey character of the soil, and it became necessary at the corners to put in very heavy poles, which were embedded in concrete and stones to prevent settling out of place after heavy rains. These poles carry the main circuit, which extends throughout the entire length of the road, and is a copper wire three-sixteenths of an inch in diameter; this is called the main conductor, for on it depends the operation of the road in case of accidents or repairs to the contact wire.

This main conductor is supplied at widely separated points by feeders, which come from the main supply at the central station. Without the use of these feeders, which can also be reinforced if necessary, the size and cost of the overhead conductors would be very largely increased. The curves are formed of a series of short chords, which approximate the central line of curvature.

The current is taken from this working conductor by a light structure on top of the car (see Figure). This consists of a low skeleton framework which carries an adjustable swivelling trunnion, having at its upper end a jaw in which is suspended a counter-balanced trolley pole, having at its extension a grooved wheel held by a spring against, and making running flexible contact with, the under side of the working conductor. The flexibility of this arrangement is very great, it being able to follow with perfect facility variations of the trolley wire two or three feet in either horizontal or vertical direction, at any speed, and around any curve. What is all important, it relieves the line of strain instead of adding to it. When getting at the end of the track this trolley trunnion is swung around so as to trend in a proper direction abaft the centre of the car. If off the line it can be replaced from the car quickly and easily in the darkest night. From the trolley the current passes through a protected wire to the lightning arrester and thence to two switches one at each end of the car, whence, after whatever commutation is necessary, it goes to the motor circuits, and thence to the wheel frame.

The return circuit is through the track, and thence by both metallic and ground circuits to the station. Each section of rail is joined to a copper ground wire, which runs throughout the length of the road underneath or alongside the stringer pieces, which is done to prevent appreciable differences of potential existing between the rails. As a further precaution, at intervals of 500ft., this ground wire is connected to an earth-plate, and at seven points widely distributed these ground plates are supplemented by heavy iron pipes sunk into iron ore, or 12in. water wells, about 25ft. deep. The ground wire is connected to the station, and there is also a main ground connection made there in a 30ft. well through a large zinc plate, and another to the entire water-works system. Some modifications of the overhead system are now being made

Digitized by Google

which will make it impossible for any accident to one section of the line to disable the remainder ; will enable the different sections to be operated independently ; and, in case of a fire which may necessitate the blocking or temporary disabling of one part of the line, will allow this section of the line to be cut out of action either automatically or at will.

Each car is fitted with a duplicate and very powerful motor equipment. This is carried entirely beneath the car body, is very compact, out of sight, and necessitates no radical change in the construction of the car. The body had to be stiffened a little and 3in. steel axles put in. One of the great objections which have been met with in applying motors, whether steam, electrical or of any other character, to the propulsion of street railways, has been the difficulty of getting sufficient track adhesion to operate the car under all conditions of track, loads and grades. Especially was this objection true in Richmond, where it was manifest that no application of a motor system could be fully successful unless the entire weight of the car and its contents were made available for traction.

One of the manifest reasons is, of course, the slippery character of the track under many conditions. Another thing should also be noted, and that is that it is almost impossible in practice to cast all wheels of exactly the same circumference, or at least so that the paths described by the lines of contact shall be the same. Moreover, on curves the wheels are all travelling over paths of different lengths. Theoretically, the wheels should be independently driven, but since this is not possible it follows that the next best thing is to drive each pair of wheels independently. It is a fact which admits of no dipute that there are conditions of track which will not permit of a car being driven from one pair of wheels only, and this difficulty is often augmented by the fact that if one pair of wheels only is used they will sometimes be leading, sometimes following ; on heavy grades, with one platform reserved for the driver, there is a very serious displacement of the centre of gravity, and there may be very much more weight upon one pair of wheels than on the other. The whole experience in Richmond has been to emphasise the value and necessity of independently driven axles.

To accomplish this, one motor is centred upon each axle, and to allow the required freedom of motion, and at the same time to preserve perfect parallelism in the meshing of the gears, and also for taking part of the weight of the motor off the body of the axle and to throw it on to the journals, one end of the motor is supported by double compression springs playing upon a loosely suspended bolt, which is supported from a cross girder in the bottom of the car.

The motors are, then, so to speak weighed or flexibly supported from the car body, and the motion of the armatures is transmitted to the axles through intermediate gearing, of compact form and great strength, so that whenever the axles are in motion there is a spring touch of the pinions upon the gears. Barring friction a single pound pressure exerted in either direction would lift or depress the motor a slight amount, and no matter how sudden the strain, whether because of a variation of load or speed, or a reversal of direction of rotation, it is impossible to strip the gears unless the steady strain exceeds the strength of the iron, the pressure on the gears always being a progressive one. The motor armature makes nearly twelve revolutions to each revolution of the car axle.

The motors, although in one sense independent, are connected with duplicate switches at either end of the car which afford simultaneous control of both machines. These motors, which are of normal capacity of 7½ horse-power each, can for a short time work up to 30 horse-power, and are capable of producing a tractive effort of over three thousand pounds at 50 per cent. efficiency.

The machines are controlled by a single movement switch, which effects the various commutations and reversals. They run with fixed brushes in both directions and under all loads. They are run without any covering, and I have no doubt of having street car motors in such condition soon that the cars will be run over a pit, and the machines washed down with a hose.

The cars can be run at widely different speeds, varying from the slowest crawl to twelve or more miles per hour. They can be started and stopped without the use of brakes in the space of three or four inches, and when making the normal running speed can, in an emergency, be stopped and reversed without brakes within less than a quarter of a car length. The starting, although prompt, is easy and without shock or jar.

Emergencies sometimes bring out qualities of motors which are unexpected, or which, at least, if counted on are rarely ever brought into play. On one occasion a man was descending a six per cent. grade with a heavy load when his brake chain parted. Seeing a sharp curve right ahead of him which he knew he would leave if he struck it at the speed he was running, he instantly reversed his machines and brought his car to a standstill, and on the rest of his trip handled his machines entirely with the motors. On another occasion a man, pssing from behind one car directly in front of another, was struck and knocked down by the dash-board. Although the car was moving at a lively gait, the machines were reversed and the wheels stopped within a foot of the man. By any other method of propulsion he would have been killed. Frequently on a ten per cent. grade, with a loaded car, the brakes have been thrown off, the machines reversed, the car stopped and started backward up hill within less than one-half of its length, a test of the most remarkable severity.

In noting the control of the car, one is struck at the remarkable character of the traction, and cannot help wondering where it comes from. Unquestionably it is in a large measure due to the fact that every pound of weight is available for traction, and that the two axles, being independently driven, can take their own speed, and each pair get the best grip.

Another thing to be noted, where the ground circuit is used, is the increase of traction due to the passage of the current from the wheels into the rails. Exactly what molecular action takes place has not been ascertained ; it may be simply heating at the contact surface, but the fact remains that the traction is very largely increased. The magnetic condition of the wheels and tracks also has some function in this increase of traction. The wheels and axles are magnetised by the method of motor construction and mounting, and also by the passage of the current through them ; the tracks are likewise magnetised by the current passing through them, and also by the rolling contact of the wheels. Yet, admitting all these aids, the results have been extraordinary.

Sixteen-foot closed cars, carrying picked loads of fifty-five to sixty passengers, and having a total weight of 15,000 pounds, are operated on the 10 per cent. grade, often with a slippery and slimy rail, and on 27-foot curves, without the use of sand or extra help.

These same grades and curves have been ascended without sand after one of the worst sleet storms which has visited this section for years. Various tests under the most unfavourable conditions have been made, cars often being required to cut their way through clay, snow, and ice when the tracks were out of sight. No severer test could have been made, and the power and tractive effort developed have exceeded the most sanguine expectations.

Cars have often been stopped and started on the heaviest grades, and in the sharpest curves. One motor has propelled two cars around sharp curves and up six per cent. grades. One car has pushed another of greater weight around the sharpest curves and up seven and eight per cent. grades both straight and combined.

I have no hesitation in saying that with a clean track, and with proper gearing, these cars could mount a 15 per cent. grade, depending on adhesion alone. During the four months' operation, although there have been troubles and changes have been made while the cars were running commercially, no car has been pulled a foot by animal power ; if any accident has occurred to a motor the car has gone along with one machine, oftentimes with heavy loads and on heavy grades, or in some cases has gone home in company with another car. One hundred and forty men, who did not know the difference between a motor and a hand-saw, have been broken in to handling these cars ; oftentimes with remarkably short training. Up to Saturday, May 4, the number of regular cars on duty had not succeeded twenty. On that day, at 4 p.m., the hour when traffic becomes exceptionally heavy, we began putting out ten open cars, starting them from the eastern car-house alternating with the closed cars, but finally banking them all up at the Old Reservoir. At 6 p.m. they were started home, and shortly afterwards these ten open cars, headed by a closed car, were all run at full speed close together down the east-bound track of Clay-street. At one time fourteen cars were on the line between Clay and Hancock-streets and the Old Reservoir, and shortly before 7 o'clock there were about twenty-two cars on the line between Capitol-square and the Old Reservoir, and at 7 o'clock thirty cars were on the line, the closed cars being very heavily loaded, many of the cars being run with two-minute intervals. The three boilers, whose capacity is 375 horse-power, were then supplying three Armington and Sims engines of 125 horse-power capacity, which were driving the six railroad dynamos, and two Westinghouse engines of 110 horse-power capacity, which were driving two alternating-current dynamos and exciters, with an equivalent load of 1,060 incandescent lamps. The mixture was enriched, and the firing of boilers became pretty active, there being, in addition to the thirty cars badly banked, about 110 horse-power taken for lighting.

The highest reading, however, on the line was less than three-quarters of the normal capacity of the dynamos, which were originally intended only for thirty cars, and the average reading for this number was only a trifle over half the normal capacity.

The figures which follow, being based upon an actual service increasing from eight to thirty cars, and extending over a period of four months under the most trying circumstances, and at the most critical and care-requiring period of the enterprise's existence, will give street railway men the most careful and liberal estimate of every possible expense attending the operation of the road which is in any way dependent upon its electrical features. The operating expenses are given under two heads—First, the central station operating expenses, and second, the road operating expenses ; the

Digitized by Google

two constituting the total cost of motive power. These are given in detail, and they will probably be found to cover every expense, although in some small ways the distribution of these expenses may be found to be changed by several months' longer running. The fuel and other incidental expenses of the station are from the engineer's record, and checked by the readings of the electrical instruments.

For thirty cars running on a double track the central station expenses are about as follows :—

52 42-100 cwt. coal, at 10 cents	$5.84	
113 70-100 cwt. screenings, at 7 cent.	7.96	
5 pints cylinder oil, at 75 cents per gallon	.47	
5 pints dynamo oil, at 30 cents per gallon	.18	
3 pounds waste, at 10 cents	.30	
Water at current rates	3.00	
Fuel, &c.		$17.75
1 day engineer	$3.00	
1 night engineer	2.25	
4 firemen	6.00	
1 cleaner	1.50	
2 dynamo men	3.50	
1 electrician	4.00	
Labour		$20.25
Lighting	.50	
Depreciation and repairs on dynamos, 3 per cent.	1.50	
Depreciation and repairs on engine and boilers 10 per cent.	4.38	
Total central station expenses		$44.38

or $1.48 per car making 80 miles.

[The central station being operated for twenty-four hours for lighting and power purposes, the lighting company has now assumed charge and rents the power to the cars at $1.60 per day.]

In estimating the road expenses, more than liberal allowance is made, but in a new enterprise it is safe to err on this side rather than attempt to claim for a system advantages which will not in practice be borne out. The expenses are then as follows :—

Oil, grease, and waste	$4.50	
Brushes	3.00	
Trolleys	2.00	
Material		$9.50
Three mechanics and one helper for thoroughly overhauling motors once a week, making repairs, adjusting brakes, &c.	7.90	
Four inspectors, two day and two night, for oiling machines and looking after brushes	7.50	
Two night inspectors, to thoroughly inspect motors after cars are laid up and see that all bolts, nuts, and connections are tight, and that everything is in good working order for the morning run	4.00	
One winder and helper for making any repairs which may be necessary and any testing which is required	3.50	
Two linemen	5.00	
Labour		$27.90
Depreciation on car work at 15 per cent.	18.00	
Depreciation on line work at 10 per cent.	4.00	
Depreciation		22.00
Total road operating expenses		$59.40

or $1.98 per car making 80 miles.

The total motive power expenses both in the central station and out on the road would not then exceed 3.46dols. per car making eighty miles, or 4.32dols. per car mile, and this includes everything except the executive and salary expenses, taxes and insurance, and is less than 40 per cent. of the cost of operation by horses with the same number of cars and under the same conditions.

But the showing is even better than this, for another fact is to be noticed, and it is an important one from an economical point of view. For example, twenty cars on duty for about eighteen hours make a mileage of from 1,500 to 1,800 per day, and if it were not for the fact that the schedule requires them to operate part of the time on a single track with insufficient turn-outs they could make 1,800 or 1,900 steadily. This, notwithstanding the fact that the speed is limited by municipal regulations. Many of the cars often run 90 to 100 miles. The same mileage and intervals made by twenty electric cars could not, under the circumstances, be made by anything less than twenty-five horse cars of the same size, and the electric cars probably carry in the aggregate just as many passengers. It follows that to get the same service with horses not only would the number of cars have to be increased, but likewise the number of horses, conductors, and drivers. The same mileage performed by horses without these cars and grades would require a stable equipment of not less than 300 horses.

With the mileage which is now made, there is an actual saving of about 125dols. per day in the motive power expenses as against operations by horses. It is hardly necessary to point out that this would pay a good interest on a pretty large investment. The capacity of the road to economically carry passengers has been made so apparent that the old City Railway, which was operated by mules, and has about thirty miles of track and fifty cars, has been bought up, and is to be equipped with motors operated from the same central station. A third line will probably be added, and in the near future every street car, to the number of one hundred, in Richmond and Manchester, will be electrically operated from one station.

MR. VERNON HARCOURT'S NEW PHOTOMETER.

The holophotometer has been designed in order to get rid of two difficulties connected with other methods of attaining the same object, viz., to measure the light emitted in every

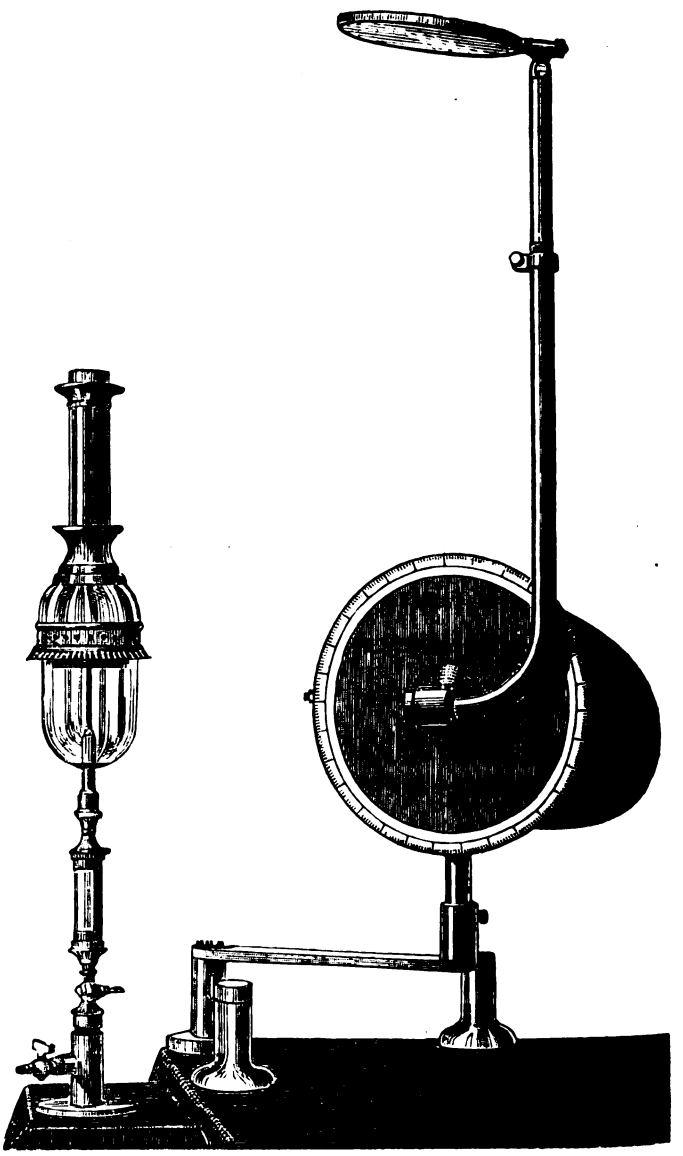


FIG. 1.

direction by any luminous source. These difficulties are:— (1) The movement of the light to be measured or of the standard lamp, neither of which is desirable. (2) The errors caused in the measurement of lamps provided with reflecting fittings, by the assumption that the flame is the zero point from which measurements should be made, whereas, strictly speaking, the principal focus formed by the reflectors should be taken as the zero point. Inasmuch, then, as this focus may be several inches away from the flame, and as the length of bar usually employed is 60in., it is evident that serious errors may be introduced by the difference between the real and the

Digitized by Google

assumed zero points. To establish the existence of such an error, and to eliminate it, two things are necessary, viz., that readings should be taken with bars of various lengths, and that the length of the bar should be very great compared with that between the real source of light and the focus formed by the reflector. Both these points are secured by the use of the holophotometer. The instrument is mounted upon a table capable of being moved nearer to or further from a fixed table containing a graduated bar, with a movable disc (say, of the Letheby pattern), and having a standard lamp fixed at the zero of the bar. The lamp to be measured is mounted upon, or is in rigid connection with, the movable table, and is therefore not moved during a series of readings.

The holophotometer consists of an axis working friction-tight in a collar supported by a vertical pillar. The axis is accurately fixed at the same height, and in a line with the centre of the disc. At the end nearest to the disc is placed a large mirror with its centre concentric with the axis, but so arranged that the plane of the mirror may be inclined and clamped at any angle to the axis. At the other end of the axis is fixed a telescopic arm carrying a smaller mirror, which is capable of being turned into any required position. The arm being rigidly fixed to the rotating axis of the instrument, to which is also attached the larger mirror, it follows that the rotatory motions of the mirrors about the axis are identical. The angles of rotation are measured by the indications upon a divided circle attached to the moving axis, which are shown by a pointer fixed to the upright support.

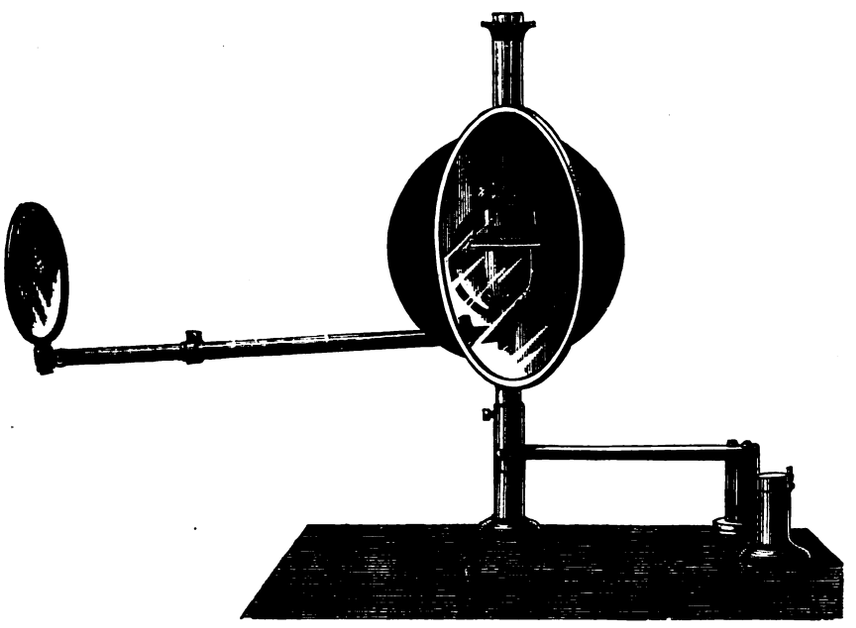

FIG. 2.

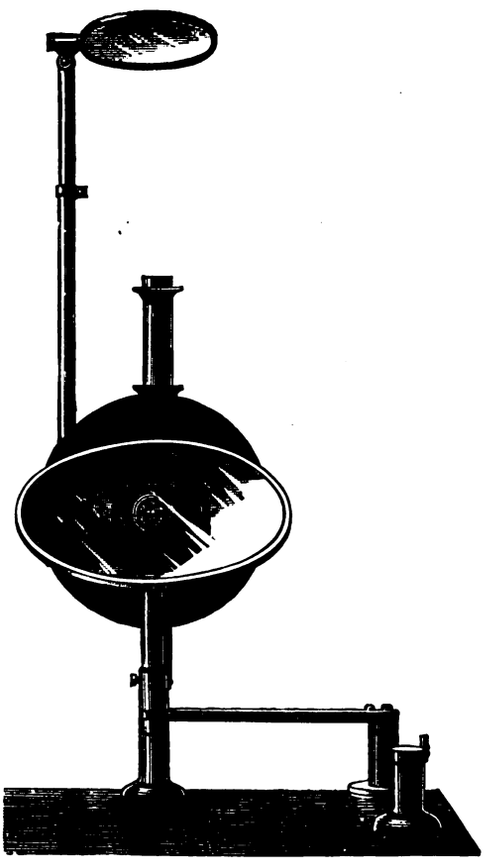

FIG. 3.

The mirrors are adjusted in such a way that the light from the lamp to be measured falls upon the smaller mirror, thence is reflected on to the larger one, and finally along the axial line of the photometer disc. As both mirrors rotate together it follows that if a horizontal beam is reflected correctly all other beams will find their way along the axis of the photometer. If, therefore, the arm carrying the small mirror be moved through various angles, it will receive the light emitted from the lamp at those angles, and the light will at every angle be transmitted along the axis of the photometer. The divided circle is made large enough to serve as a complete screen of all direct light, and only the light falling on the small mirror can find its way to the disc. In order that absolute, as well as comparative, tests may be carried out, only one additional measurement need be made. The direct horizontal light is measured without the interposition of the holophotometer (which is mounted so as to be easily moved out of the direct line); then the mirrors are interposed, and a new measurement made. The additional path travelled by the light is allowed for in calculation; and thus the absorption of the mirrors is found once for all for the particular character of light under measurement. It is only necessary afterwards to multiply subsequent values by this coefficient of absorption in order to obtain absolute measurements at various angles.

The employment of mirrors in photometry has sometimes led to serious errors; but it will be seen by the foregoing description that inasmuch as the relative angle of the mirrors is never changed, and as their absorption is easily calculated and allowed for, the only objections to their use have been guarded against and avoided.

In order to eliminate the second source of error mentioned above, viz., that arising from the formation of a principal focus, it is only necessary to take a series of readings with the table in one position, and then move it to a greater distance and take another series. If a focus is formed at a sufficient distance to produce an appreciable error, it will clearly appear in the difference between the readings at the two distances, and then it is only necessary to wheel the table to such a distance that the discrepancy is inappreciable. In other words, this is equivalent to using a bar of sufficient length to make it practically infinite compared with the distance between the focus and the real source of light.

The instrument has been designed specially for use in light-house work, where it becomes of the highest importance to measure accurately the total light given by any lamp, and not only that emitted in any one direction which may or may not be the maximum.

Preliminary experiments made with the instrument by Mr. Stepney Rawson, at the works of the Woodhouse and Rawson Electric Manufacturing Company, have shown what a valuable instrument it is for the determination of the commercial value of various lamps, as well as for assisting in the many difficult problems of the diffusion and reflection of light. The absorption of the two mirrors used is, as already mentioned, stated to be only 1·8 per cent., but a series of experiments are to be made upon this point.

We show here three views of the instrument:—

(I.) As seen from behind, showing the divided scale.

(II.) Looking from the photometer disc, showing how the horizontal light from the lamp is transmitted to the disc.

(III.) Looking from the photometer disc, showing how the vertical light would be transmitted to the disc.

The instrument is supplied by the Woodhouse and Rawson Electric Supply Company, 11, Queen Victoria-street, E.C.

RANSOMES, SIMS AND JEFFERIES' ENGINES.

Messrs. Ransomes, Sims and Jefferies (Limited), Orwell Works, Ipswich, have recently brought out two portable engines of 6 and

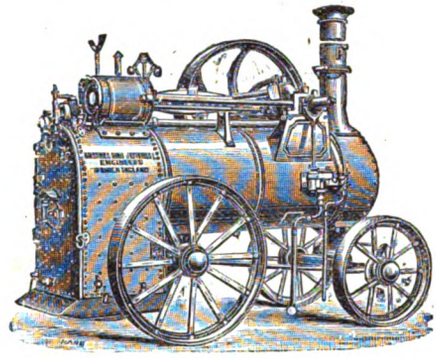

FIG. 1.

8 horse-power respectively, of new design, which possess several noteworthy features. The cylinders are of increased diameter, steam jacketed, and lagged to prevent condensation and radiation of heat. The crank shafts are supported upon wrought-iron brackets riveted to the boiler, and the bearings on each side are provided with vertical and lateral adjustments; the governors are of the high-speed class, very sensitive, in direct communication with a double-beat piston valve, and have complete control over the engines, maintaining a regular speed. The boilers have raised-top fire-boxes, giving ample steam space, and a large manhole in the side of the fire-boxes gives great facility for cleaning. Many of these portable engines have been used for small or temporary electric light installations. This engine is illustrated in Fig. 1.

Messrs. Ransomes' 20 horse-power compound undertype engine is a fine specimen of workmanship and finish, and where economy of fuel is a consideration will be found exceedingly valuable. The cylinder and working parts are mounted on a strong wrought-iron girder frame; the boiler is placed over the engine on the same frame, resting at the smoke-box end on the cylinder, the frame being extended beyond the crank shaft to form an ash pit for the fire-box.

These engines are specially adapted for export, not only on account of the ease with which they are fixed, but as the boiler can be detached from the engine and the girder frame taken to pieces, the weight of the packages may be considerably reduced so as to facilitate transport. This is a matter of the utmost importance in many countries. Another advantage of this type of engine is that it occupies very little space and requires no expensive foundations.

Messrs. Ransomes also supply compound engines of the same type with separate or detached boilers, as shown by our illustration (Fig. 2), two boilers often being found more convenient than one larger boiler on account of the greater facility in transport already referred to. They are made of mild steel plates throughout, and the fire-boxes when desired may be of extra large dimensions for burning every description of inferior fuel.

The 8 horse-power short stroke stationary engine shown in Fig. 3 has the bed-plate, cross-head guides and plummer-blocks for crank

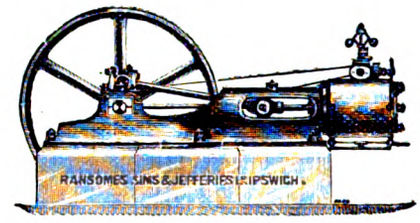

FIG. 3.

shaft all cast in one piece, the cylinder, with its valve-chest, being bolted to the end of the engine frame. This design is very strong, neat and compact, and well suited for electric light work.

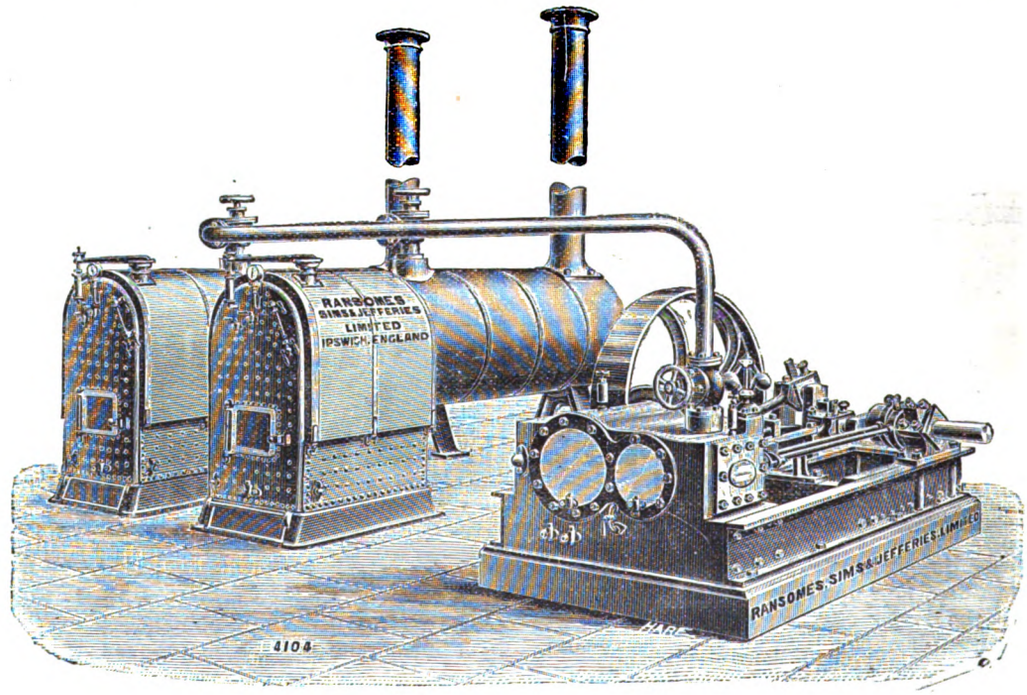

FIG. 2.

THE COX-WALKER SWINTON MAGNETO-BELL AND GENERATOR.

The system of magneto-bells which we illustrate herewith bears some resemblance to the Abdank-Abakanowicz system which was brought out last year. It is, however, sufficiently distinct to have involved separate invention, and the details have been carefully and ingeniously worked out, The current is obtained from a little magneto-generator (Fig. 1), provided with a Siemens shuttle-wound armature. A wing-shaped handle is attached to this shaft, whose motion is confined to an arc of about 30°; when held between

Digitized by Google

the finger and thumb and moved to and fro the current generated makes a stroke on the bell at each reversal. There is no gearing, and the whole apparatus is reduced to the simplest and most compact form.

Several patterns of bells are made. The one which we illustrate in Fig. 2 is, we believe, the first self-contained magneto-bell which has been constructed. It consists of the usual electro-magnet with polarised armature, and is well designed and finished. These

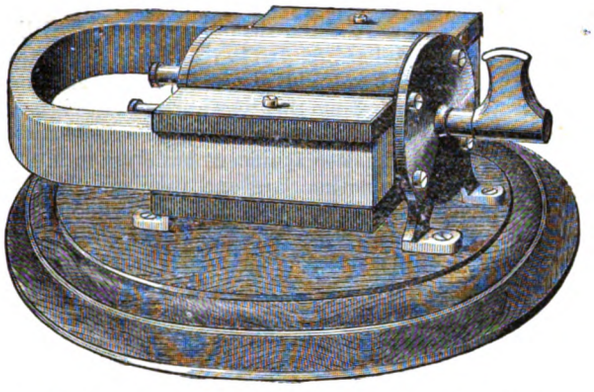

FIG. 1.—The Cox-Walker Swinton Magneto-Generator.
The handle moves to and fro about 30deg. only.

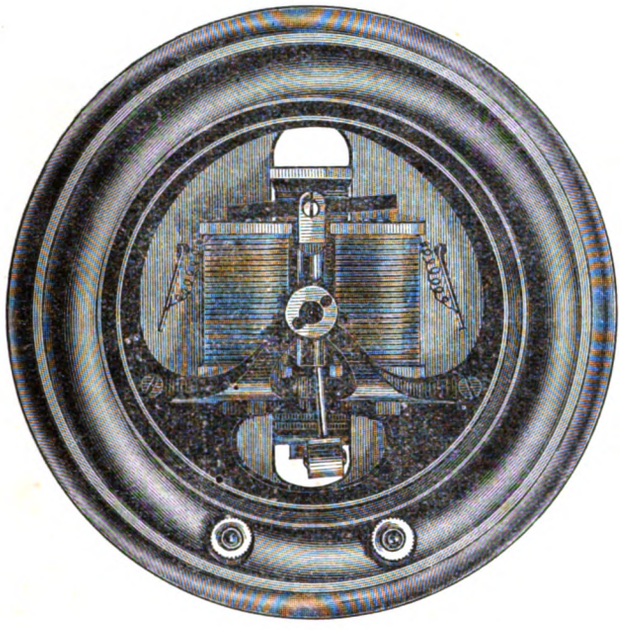

FIG. 2.

instruments are supplied by the Equitable Telephone Association, and are the joint invention of Messrs. Campbell Swinton, and Cox-Walker.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *July 21st*, 1888.

The New York Board of Electrical Control, which has been pushing matters so vigorously here in regard to the overhead wires of the arc light companies, is now agitating a subject of even greater importance, viz., the admission of the alternating-current system into the city for the purpose of commercial supply and distribution. The discussion of the matter has been precipitated by the publication in the *Evening Post* of a letter from Mr. Harold P. Brown, an electrical engineer, criticising the alternating current as "damnable," and proposing that no alternating current with a higher E.M.F. than 300 volts shall be used. Mr. Brown went so far as to say;—"The only excuse for the use of the fatal alternating current is that it saves the company operating it from spending a larger sum of money for the heavier copper wires which are required by the safe incandescent system. That is, the public must submit to constant danger from sudden death in order that a corporation may pay a little larger dividend. I do not know a single disinterested electrician of high standing who does not condemn the alternating system." He asserted that the Board should forbid the use of the alternating current in this city, therefore, except under the conditions specified. This letter attracted so much attention that the Board determined to make it the basis of an investigation on the subject, and invited the attention to it of those interested. In this manner it comes to pass that the battle of the currents is being fought this week in New York. The first meeting for the consideration of the subject was held on the 16th inst., when a number of interesting documents were filed. One of these was a letter from Mr. W. H. Browne, the secretary and manager of the Safety Electric Light and Power Company, which proposes to introduce the Westinghouse system here. Mr. Browne stated that the Westinghouse alternating system for incandescent lighting is in successful daily use in some 82 central stations, located all over the country, that 45 more are being built, and that the average rate of increase at the present time is two stations per week. These stations have a capacity of from 2,000 to 18,000 lights each, yet in no case has there occurred, says Mr. Browne, any death from accident or any fire. Mr. Browne states that the station to be put up would be built on the west side of the town, right on the bank of the Hudson River, adjoining the Sawyer-Man lamp factory, and that its currents would be conveyed underground, the wires being lead-covered and placed in conduits. The converters will be placed against the cellar wall, or in the coal vaults under the side walk. A primary potential of 1,000 volts will be used, reducing in the secondary to 50 volts. Accompanying this letter was one from Mr. T. Carpenter Smith, who has had charge of the big alternating system in Pittsburg. Mr. Smith gave his evidence as to the danger attending the use of the alternating current, and said that, while disagreeable, it was far less perilous than a direct current of the same potential. He had received the full 1,000 volts of alternating current, not once, but half-a-dozen times, and he had also received a direct current in the same way; and while the direct current always made one ill for some time after the shock, the alternating current left no such effect. He had seen five or six men get an alternating-current shock in a similar manner. He had himself pulled one of them off the bare switch-board wires; although the man's hands were badly burnt he had been at work again in half an hour, and had in the meantime walked by himself to the doctor to get his wounds dressed. A communication was read from Mr. Ralph W. Pope, to whom Mr. Brown's proposed rules had been submitted by the Board. Mr. Pope pointed out that the Board was undertaking a very difficult thing, if not an impossible one, in fixing upon an arbitrary standard which an electric current should not be allowed to exceed. The pith of the policy to be pursued, in his opinion, therefore, was not to fix upon any particular number of lamps to be operated on one circuit, or any standard of voltage which must not be exceeded, but rather to insist on such methods of construction, and the use of such material, that the current would always be confined to its designated conductors. This implied the use of a conductor of ample size for the current to be employed, and properly insulated at all points, the insulating resistance increasing with the voltage.

A letter was also read from Mr. H. M. Byllesby, the vice-president of the Westinghouse Company, confirming the statistics already quoted as to the growth of the alternating business, and stating that as to the alleged impossibility of the operation of the system on an underground circuit, any allegation of such a character was absolutely and entirely false. The company at Denver was operating very successfully under ground, with a distributing capacity of over 12,000 16 candle-power lamps. At Springfield, Mass., the underground system had a distributing capacity of 2,100 lamps; in Philadelphia, the Keystone Company were distributing 2,600 lamps.

Digitized by Google

Supplementary to this was a communication from Mr. O. B. Shallenberger, electrician of the Westinghouse Company, discussing the question of shock or of danger of fire. Mr. Shallenberger held it to be evident that while the passage of the direct current through the human body for even a moderate length of time may be sufficient to so decompose the fluids and tissues of the vital parts as to produce fatal results very quickly, a current of the same quantity of rapidly alternating potential might produce only a shock to the nerves without any organic change, and consequently without permanent or even serious danger. Speaking of the insulation on the converters, Mr. Smith said that among the several thousand now in use he had yet to learn of a single instance in which any connection had been discovered between the primary and the secondary wires, although the converters had been in use under every conceivable condition. In point of fact he regarded the converter as an extra safeguard to the consumer, as it was a protection from lightning. Under all other conditions than the burning out of the converter by lightning, or its destruction by fire, the nature of the insulation between the primary and the secondary circuit was so perfect that it was almost impossible for any connection to occur between them.

Mr. S. C. Peck, the expert of the Thomson-Houston Company, also submitted a statement, in which, taking up several points presented by Mr. Harold P. Brown, he held, first, that the alleged comparison between the effects from a medical or galvano-faradaic coil of the alternating dynamo did not exist; that the death-dealing quality of the current from dynamos having open coil armatures is a conjecture; that placing a shunt of high resistance about the terminals of the dynamo is impracticable, and would but partially compensate for the after or extra current, which was regarded as so awful; that it was not clear that death was caused by the after current; and that finally putting all such matters aside as having little to do with the question at issue, it was absurd to make 300 volts the limit for alternating-current service, because practical demonstration extending over a period of two years had shown that with the proper devices there was no danger even with a thousand volts. What was needed in regard to electric currents was *control* and not *prohibition*.

Another expert view of the case was presented by Mr. M. M. M. Slattery, the electrician of the Fort Wayne Jenney Company, which has now introduced the alternating-current system. Mr. Slattery remarked, as to underground systems, that in point of fact a low tension current of 220 volts offered a far greater strain upon insulation than an alternating current at 1,000 volts. With low tension continuous currents during the hours of heaviest lighting a loss of some 20 to 25 per cent. occurred in the conductors, and hence the trouble and strain which was not experienced with the alternating current, despite its higher E.M.F., the strain from which he characterised as more apparent than real This long string of documents closed with one from Prof. Henry Morton, the well-known president of the Stevens Institute of Technology, who took up the cudgels for overhead wires, claiming that there were as many dangers with the underground as with the aerial system. As to danger from shock, Prof. Morton said there was certainly nothing in the results of experiments and observation so far which would warrant us in requiring less protection in the use of one sort of current as compared with the other, or in excluding one where the other was admitted. Prof. Morton challenged Mr. Brown as to his statement about the universal condemnation of the alternating system by leading electricians, and proceeded to criticise Mr. Brown's proposed rules in a very sharp manner. It may be mentioned that Mr. Brown, in his talk on the alternating system, laid himself open to pointed retort from the fact that he had himself put on the market a converter for the use of incandescent lamps on direct arc circuits of 2,000 or 3,000 volts.

While speaking of the Subway Board, I may mention the fact that Broadway is once more undergoing an upheaval, as new conduits are being laid for more wires. The consequence is an incessant blockade in the midst of the summer dulness, and the dust is perfectly maddening. This breaking up of the streets is fast becoming an intolerable nuisance. One of the Philadelphia papers has been complaining very bitterly about the everlasting ripping-up of the paving in the streets there, and it publishes a sectional view of Market-street, showing the number of services that now underlie the granite blocks. It protests against any further interference of this kind with municipal cleanliness and convenience, and insists that all work of this nature should hereafter be carried on in subways similar to those in Paris.

It is announced from Boston that the Americal Bell Telephone Company there has invested in real estate with the object of putting up a fine office building for its own accommodation. This investment of telephone earnings in real estate is becoming quite a notable feature. Here, in New York, the Metropolitan Telephone Company has a magnificent building in Cortlandt-street, and is to have another fine one uptown. In Chicago, the Telephone Company has just taken possession of a very fine building of its own; in St. Louis, the local company will also soon have a beautiful palace. At Louisville there is a fine telephone exchange, and in Pittsburg and Providence the new quarters are very handsome and comfortable. It looks as though, in a few years, all the leading telephone exchanges in the country will be magnificently housed—far more so, in fact, than the telegraph offices are.

It is generally accepted here as a fact that the two years' struggle among the cable companies has about exhausted all the combatants, or at least finds them ready and willing to come to terms. The announcement of impending peace has been hailed with satisfaction, and has contributed in no small degree to the improvement of the stock market. It is said that the new rate will be 25 cents a word, but on this point you are probably well informed in England by this time. It is reported that all the conditions have been adjusted, and that the only one remaining for settlement is the number of words which shall be accepted as a minimum for a single message. It is understood here that the Commercial Cable Company, with their two cables, have been doing about 40 per cent. of the whole business, which, of course, would be more than their share *pro rata*, and it is further stated that they have cleared $200,000 profit during the past year; although that is exceptional from the fact that no repairs have had to be provided for, and no provision has been made for renewals. The Commercial Cable Company claim that they have been willing to make reasonable terms for some time, but that the delay has arisen from the fact that there was more fight inside the pool than outside of it.

The Paper which Mr. Frank J. Sprague read last month before the American Institute of Electrical Engineers, has just been published by the papers, and proves a contribution to electrical literature of more than ordinary value. I sent you a synopsis of it at the time it was delivered * It will be remembered that Mr. Sprague, as an exemplification of many of his theories and much of his practice, cites his big road at Richmond, Va., which is now carrying from 75,000 to 100,000 passengers per week, and which has been put into operation in the face of endless difficulties and discouragements. The Sprague Company, which six months ago was not turning a single wheel, now has in operation, or in course of construction, nearly 200 cars, at Richmond, Va., Manchester, Va., Davenport, Iowa, Akron, O., Steubenville, O., Carbondale, Pa., Wilkesbarre, Pa., Harrisburg, Pa., Scranton, Pa., Lafayette, Ind., St. Joseph, Mo, Wilmington, Del., Hartford, Conn., Salem, Mass., and Brocton, Mass. This shows something like activity in street railway work, and it may be added that the Thomson-Houston Company has just started a road at Pleasant Beach, Mass., and the Daft Company one at Meriden, Conn.; while the Reckenzaum storage system has just gone into operation on one of the roads in Philadelphia.

I believe I have already referred in a previous letter to the rumours current regarding the combination between the phonograph and the graphophone interests. The announcement is now formally made to that effect. A company has been formed which will control both machines. The purchase includes all

* This Paper is one of so much interest that we have considered it worth while to give a fuller account of it, which will be found elsewhere in the present issue.—ED. *E.*

Digitized by Google

the improvements which Mr. Edison may make in the phonograph during the next 15 years, as well as those which may be made in the graphophone in a similar term, but it does not affect the foreign rights in either case. I hear it stated that the introduction of the graphophone in England will be made by Mr. Hy. C. Edmunds, who is well known in English electrical circles, and who is at present visiting this country. The rumour in Wall Street this week that the Edison phonograph rights for England had been sold to a syndicate for $250,000 is absolutely denied.

The decisions in England this week, reported by cable in the *Electrical World*, upsetting the Gaulard-Gibbs patent, and invalidating one of the ruling Edison incandescent lamp patents, have been received with considerable interest, and are now the subject of general comment. The chief question that arises is as to the effect of these decisions on corresponding patents in this country. With regard to the alternating-current patent, it is said that it was drawn in this country with far greater skill and precision than was applied to it in England, and that it was as strong as Mr. F. L. Pope, a master in his art, knew how to make it. The decision may, however, it is said, offer certain advantages to the concerns here which do not regard the Westinghouse patents as valid and are manufacturing alternating-current apparatus. As to the decision on the Edison patent, it is claimed on the one side that the principles which governed in England will govern here, and on the other side it is argued that the ruling in the case would have no influence whatever, the patent laws, as everybody knows, being very different in the two countries. Very little can be said till a fuller report arrives. Mr. Park Benjamin, however, does not wait, but is quoted in one of the dailies as saying:—"Of the American patent little need be said, on the principle *de mortuis*. It expired recently at the hands of Judge Wallace, because of the haste of the promoters in getting sundry prior foreign patents on the same thing, which, dying a natural death, dragged the patent here down with them."

CORRESPONDENCE.

UNIPOLAR INDUCTION.

TO THE EDITOR OF THE ELECTRICIAN.

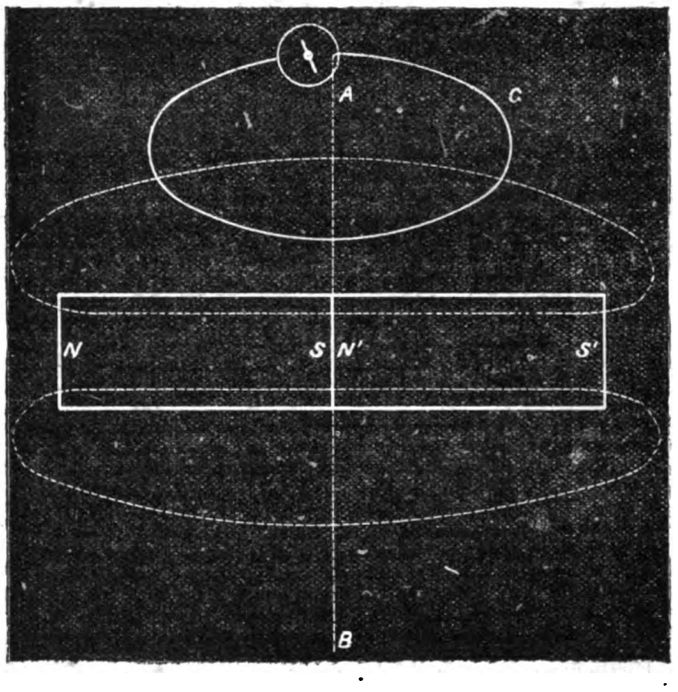
SIR: A line of magnetic force, according to Maxwell's teaching, may be regarded as a sort of vortex ring or axis of molecular vortex motions taking place in the molecules of the ponderable or imponderable matter situate within a magnetic circuit.

I can displace these lines of force, in the case of any magnet, without moving the magnet itself, by introducing into its field a lump of iron, when the lines concentrate themselves within it at the expense of the remoter portions of the field. I may also displace the lines *holus bolus* by moving the magnet bodily, in which case the field remains intact both in form and in strength, having moved *quasi*-rigidly with the magnet.

Regarding these displacements of lines of force, it seems certain, that in neither case do they represent anything more material than a transference of the vortex motions to fresh matter or ether, just, for example, as waves, representing so much energy, may move from one situation to another without taking the water along with them. When this particular form of energy is made to traverse space, it sets up E.M.F. in the bodies traversed, by virtue of the mechanism by which the energy is propagated from molecule to molecule. The amount and the direction of this E.M.F. depends upon the rate of the propagation, and its direction relatively to the direction of the vortex rotations, and sets up current in the bodies traversed (provided there be a path and no opposing E.M.F.) proportional to their conductivities.

The important question which Faraday and Plücker regarded one way, Weber another, Ellund another, and so on, is this. When a magnet rotates about an axis, does its energy (the lines of force) rotate with it, in the sense that the vortex motions are passed on from atom to atom in a strictly circular direction? For instance, when the field is not uniform about the axis of rotation, and the magnetic intensity accordingly fluctuates at every fixed point in the field, or when the magnet is a straight cylinder and rotates about its axis, and there is no such fluctuation? In the latter case, the energy being absolutely constant in amount at every fixed point in the magnetic circuit, does anything but the magnet rotate? Is the energy of the field propagated from atom to atom in the circular direction at a uniform rate, and with the same angular velocity as the magnet; or does this circular propagation take place in the magnet itself while the energy of its lines of force remains fixed, or does one portion of the lines rotate and the other stand still?

Mr. Tunzelmann has not set this question at rest. In his concluding paragraph, p. 263, Article V., on "Unipolar Induction," he says (speaking generally of several experiments described):—"The results of these experiments follow at once from the theory which I have endeavoured to show must be the true one, that the lines of force revolve with the magnet, for the area of the circuit continually increases during the rotation." He proceeds to point out the truth of the corollary that when the magnet is fixed so are the lines of force.



Suppose I take two equal cylindrical magnets, N S and N' S', and mount them in line as shown, the field of the one becomes the field of the other. What happens when the magnets are rotated in opposite directions? The external field is common to both magnets; does each magnet control its own half so that the lines on either side of the equator A B rotate with the magnet on their respective sides? and would a circuit, C, fixed in the position shown, "continually increase in area"?

In his article on "Unipolar Induction," in to-day's *Electrician*, p. 366, Mr. Tunzelmann refers to an observation of Hoppe's, whose views he agrees with, that when the core of an electromagnet revolves—the exciting coil being fixed—the lines rotate with the iron core, just as they suppose them to do in the case of a permanent magnet. Suppose this core to be made up of two iron cylinders, one within the other, when one of these rotates, does that portion of the lines belonging to it rotate, the others remaining stationary?—Yours, &c.,

R. SNOWDON.

Staveley Ironworks, Chesterfield, 28th July, 1888.

BATH AND THE ELECTRIC LIGHT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I noticed your leaderette on the above subject which appeared in *The Electrician* of the 27th instant, and shall be pleased to give you the information you ask for.

Digitized by Google

First, the proposed local company will be worked on as economical a basis as possible. In fact, like the Taunton Electric Lighting Company, it will be practically a consumers' supply company. The directors will receive no fees unless a dividend of five per cent. on the total capital is paid, and even then their remuneration will be but nominal.

Secondly, we propose using a valuable water-power, situated in the centre of the city, for which we have already obtained the right of purchase, whereas others who tendered probably estimated for steam power only.

As I originated the first electric lighting company in the country that paid a dividend of five per cent. on its total share capital out of its earnings upon the mere supply of light, you may take it for granted that no efforts will be spared on my part to make the Bath Electric Lighting Company as successful as the Taunton Company. I shall probably be the largest shareholder, and accept the position of managing director.

I may mention that the desire for the introduction of the electric light into several towns in the West of England has been brought about entirely by my efforts, and it was generally assumed that I should be in a position to send in a lower tender than anyone else. In fact, had any tender been sent in which was apparently lower than mine, it is not improbable that none would have been accepted, as was the case when the Maxim-Weston Company sent in a lower tender when the metropolitan authorities were on the eve of accepting the tender from the Anglo-American Brush Corporation for lighting the streets of the City.

This action of the Maxim-Weston Company I consider to be one of the most unfortunate incidents that have come under my notice in connection with electric lighting. It was not only a loss to the Brush Corporation, but tended to retard the electric lighting industry in general.—Yours, &c.,

Bath, 30th July, 1888. H. G. MASSINGHAM.

THE LIGHTING OF EASTBOURNE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I trust you will be able to spare a short space in your valuable columns in order to prevent any misunderstanding which may arise from the letter in your last week's issue, from Mr. Willoughby Smith, with reference to the arc light at Eastbourne. We are sorry to hear that he was displeased with the steadiness of the arc lamps on the Parade, and cannot but think that he must have seen them at some disadvantageous time, as the Corporation have only recently complimented the Eastbourne Electric Light Company upon the satisfactory working of these lights. We are, however, quite aware that better results might be obtained if the contract price would allow of a better carbon being used. The light given by a powerful search-lamp and that of an ordinary arc lamp (absorbing only 45 volts 10 amperes) seems to us incomparable.

We are pleased to hear that Mr. Willoughby Smith has heard good accounts of the incandescent light. He is doubtless not aware that the lighting by incandescent lamps as supplied to the town hall and municipal buildings, churches, hotels, clubs, private houses and shops, is run on the Lowrie-Hall system, and that the Parade arc lamps are the remains of the original system that was erected nearly seven years ago.—Yours, &c.,

117, Bishopsgate-street Within. HAMMOND AND CO.

Berne.—The directors of the Felsenau (Switzerland) Spinning Company have prepared plans with a view to increasing by 1,500 horse-power the hydraulic force at their disposal, with the intention of supplying electric motive power and light to Berne. The communal authorities of Berne, however, have declined to sanction the necessary works, on the ground that the Berne municipality has at its command sufficient hydraulic power of its own to provide electric power.

Removal.—The Bernstein Electric Lamp Company, Limited, notify that they have removed their offices to 2, Marlborough Mansions, Victoria-street, Westminster, S.W.

Cuba Submarine Telegraph Company (Limited).

Report of the directors for the half-year ending 30th June, 1888, to be presented at the thirty-fourth ordinary general meeting of shareholders to be held at the offices of the Company, 61, Old Broad-street, London, E.C., on Wednesday, the 8th inst., at 1 o'clock:—

2. From the accounts it will be seen that the gross receipts (including the balance brought from last account) amount to £24,274 19s. 8d., and the gross expenditure (including the half of the annual payment on account of the 1881 cable, and the expenses in connection with cable repairs) to £6,879 2s. 3d., leaving a sum of £17,395 17s. 5d. to the credit of the revenue account.

3. Of this the sum of £6,000 has been added to the reserve fund, increasing that fund to £80,000.

4. The dividend on the Preference Shares will absorb £3,000, and leave £8,395 17s. 5d., out of which the directors recommend the payment of a dividend on the Ordinary shares at the rate of 9 per cent. per annum, free of income tax, the balance, £1,195. 17s. 5d., being carried forward to the current half-year's account.

5. The Batabano-Cienfuegos (original) cable broke down on 3rd February, and was repaired on 18th idem. This cable not being duplicated, messages were forwarded during the interruption over the land lines of the Government. All the cables are now in good working order.

6. The Director who retires from the Board at this time is Mr. Horatio J. Perry, who, being eligible, offers himself for re-election. Mr. Thomas Greenwood, the auditor, also retires, and offers himself for re-election.

PATENT RECORD.

RECENT APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

9,825. W. MACKIE. London. Improvements relating to switches for electrical purposes. July 6, 1888.

9,854. LARS BRISTOL. London. Improvements in and connected with secondary batteries or electrical accumulators. July 6, 1888

9,907. M. VON DOLIVO-DOBROWOLSKY and THE COMPANY ALLGEMEINE ELEKTRICITÄTS-GESELLSCHAFT. London. Improvements in electric current and tension meters. July 7, 1888.

9,910. G. KAPP. Manchester. Improvements in and relating to continuous-current dynamo-electric machines. July 7, 1888.

9,912. G. HUGHES. London. A combined automatic magic lantern and electric apparatus for mechanically exhibiting in succession, by day or night, views, photographs, or other subjects consecutively, whenever desired. (Victor Bonnet, Hippolyte Lissagaray, Armand Richard, A. Richard and Nephtali Grumbach, France). July 7, 1888.

9,927. G. V. FOWLER and E. W. LANCASTER, trading as Fowler, Lancaster and Co. London. Improved electrical make-and-brake switch for charging circuits of secondary batteries, and automatic cut-outs for other circuits. July 9, 1888.

9,928. G. V. FOWLER and E. W. LANCASTER (trading as Fowler, Lancaster and Co.) and E. J. PENN. London. Improvements in electrical regulators and armatures for dynamo-electric machines and motors. July 9, 1888.

9,991. W. R. LAKE. London. Improvements in magneto-electric apparatus (W. Humans, United States). (Complete specification.) July 10, 1888.

10,088. J. V. SHERRIN. London. Improvements in and connected with primary batteries. July 11, 1888.

10,092. A. L. LINEFF. London. Improvements in the means or apparatus for supplying electricity to tramcars or other vehicles. July 11, 1888.

10,093. J. S. LEWIS. London. Improvements in magneto-electric calling or signalling mechanism used for telephonic or telegraphic purposes. July 11, 1888.

10,102. W. R. LAKE. London. Improvements in electric batteries (Lacombe and Co., France). July 11, 1888.

10,107. C. S. SNELL. Cornwall. Improvements in casing used for electrical conductors. July 11, 1888.

10,194. A. C. COCKBURN. London. Improvements in electrical switches. July 13, 1888.

10,209. F. V. MAQUAIRE. London. An improved electric regulator. July 13, 1888.

10,245. E. PERRETT. London. Improvements in and connected with electrical safety cut-outs. July 14, 1888.

10,239. N. W. WALLACE. London. Improvements in electric logs. (Percy Scott, H.M.S. "Edinburgh," Malta). July 16, 1888.

10,492. S. C. SNELL. Saltash. Improvements in holders for incandescent electric lamps. July 20, 1888.

10,515. E. ROSSEAU. Leyton. Improvements in instantaneous make and break electric switches. July 20, 1888.

ELECTRICAL TRADES AND THE LONDON CHAMBER OF COMMERCE.

On Friday last a meeting was held at the London Chamber of Commerce, Botolph House, to further consider the proposal to form an Electrical and Allied Trades Section of the London Chamber of Commerce. Mr. R. E. Crompton occupied the chair.

The CHAIRMAN, in opening the proceedings, said that since the meeting held a fortnight ago upon the invitation of Mr. Murray, an informal meeting had been held at the Holborn Restaurant, when twenty-eight gentlemen connected with the electrical trades had added their names to the list, so that the numbers had now reached 60 or 70, and with a little canvassing he thought they could be increased to 100. Such a number would form a very respectable section of the London Chamber of Commerce, and would be fit to run by itself. The meeting at the Holborn Restaurant was very unanimous on the subject of the necessity for the union of the trade in the form proposed. That being so they were encouraged to hope that they would find in this section properly constituted that body to represent their trade interests which they had been so long looking for. It had been at first suggested that they should have a separate society, and that suggestion had been warmly supported by various technical newspapers. Unfortunately, it fell through, as there were considered to be insuperable difficulties in the way. He could never see those difficulties himself. Then a few gentlemen belonging to the Dynamicables, which was a purely dining society, thought a society might be formed within it for the protection of their mutual interest. But immediately he received Mr. Murray's circular, and found that they could have the use of all the working machinery of the London Chamber of Commerce, he saw at once they could attain their end with much less trouble and loss of time by at once enrolling themselves members of the Chamber in sufficient numbers to constitute a section. They were now in a fair way to do that, and he invited suggestions from the gentlemen present as to whether the next step should be the formation of a provisional committee to organise a section, or whether the committee should be a management committee, and whether they should appoint permanent officials. He was not in favour of taking the latter step until the section had assumed a more important form. The country firms were practically unrepresented at this meeting, and it would be unfair to appoint a permanent Board of officers upon the votes of London members only. He wanted the new section to be one in which they could air their grievances and agree on co-operative action with regard to questions which concerned all equally, and he thought that, as very important matters would be dealt with this autumn, if anything could be done before the holidays towards constituting such a section, it would be so much the better for the electrical trades.

After a few remarks from Mr. LANE-FOX,

Digitized by Google

Mr. H. S. PRICE said he thought their present duty was to form a provisional committee, and to enrol members. Later on sub-committees could be formed.

General WEBBER then suggested that the proposed committee should be no more than a committee of management, and that it should be clearly understood that when the committee came to debate the many questions which would occur to all as being matters of great interest to the general body, then every member might have an opportunity of joining such sub-committee as might be appointed to deal with each subject. It was just possible that the proposed new section might end in being represented by a committee with whose views a large number of the members who were not on that committee might not agree, and such an anticipation might deter gentlemen from joining.

Major FLOOD PAGE said they were met to see whether the electrical trade thought it advisable to have a section in the London Chamber of Commerce. If they did think so, then it was important that they should appoint an organising committee, who, after consideration, would draw up a report calling the Electrical Chamber together again, and then, if everybody approved, join the Chamber of Commerce. There was one great advantage, they must bear in mind, in connection with such an organisation. It would be the first time that the telegraph interests, the telephone interests, the light interests, and all the other interests in connection with electricity, would be working together. This was to be an Electrical and Allied Trades Section, and there would probably be a few representatives on the permanent committee on each branch of the trade. He agreed with Mr. Crompton that the time had come when they ought to organise themselves, and also that they would gain more advantage by joining the London Chamber than if they started an independent organisation. He concluded by moving a vote—

"That an organising committee representative of the electrical trade be appointed this afternoon, with a view to organising an Electrical Section under the London Chamber of Commerce, such committee to remain in office until the permanent committee be appointed."

Mr. GARCKE, in seconding the motion, suggested that the number of the committee should be specified, and that the date should be fixed upon which to report It was very desirable that they should go cautiously to work in the first instance, as there were many intricate matters to be considered, and therefore he strongly advocated the formation of a provisional committee now, who could take into consideration the general bearings of the question, and then report to the general body.

Mr. RAWSON said they were all in sympathy with the views expressed by the previous speakers. In his opinion, the reason why so many of the attempts which had been made had broken down was that perhaps those interested had worked it too much in the form of a clique. It was very important that the movement should be widespread, and for that reason he felt inclined to move that the list of the provisional committee be kept open. No doubt there would be certain members of their body who ought to belong to that committee of whom the gentlemen present might not think of at that moment. If the list were kept open, then gentlemen in the country might feel that they had a chance of being represented upon the committee.

Mr. C. DEXTER BARKER agreed with Mr. Rawson.

Mr. TROTTER, upon the invitation of the Chairman, then related the steps which he had taken to bring about such an union of the trade. He thought they were now taking the best road to success.

Mr. WHARTON concurred in the resolution. The only doubt in his mind was, how the committee should be elected.

Major FLOOD PAGE then handed in his resolution to the chair in the following amended form, so as to meet the suggestions of the previous speakers :—

"That an organising committee of six representatives of the electrical trade be appointed this afternoon with a view to organising an Electrical Section under the London Chamber of Commerce, such committee to report to a meeting of the electrical trade about the 15th of September; the committee to remain in office only until a permanent committee be appointed, the committee to have the power to add to their numbers."

The CHAIRMAN asked Mr. Murray, the Secretary of the London Chamber of Commerce, what, according to the practice of the London Chamber, was the proper name to give to the proposed committee.

Mr. MURRAY said that up to the present the Chamber had only one general term—a Trade Section Committee—for all their sectional committees, but it was within the power of each such committee, the members of which were always elected by the whole body of members belonging to that section, to nominate any sub-committees which they might desire. There could be a standing sectional committee, and then at any particular moment for any special question which they wished to study they could nominate a special committee. If, in addition to that, they wished such a standing committee for management purposes only, it would be within their power to have such a committee. The Council would leave their hands entirely free, but it preferred to have the one name in the printed list of the Trade Section Committee. Whether they subdivided the sectional committee according to the trades, or according to the idea which he believed Mr. Crompton had, of engineers only, and engineers and electricians, was entirely according to their wish.

General WEBBER said his desire was that the members of the section should not feel that they had named a council in the same way as societies had, upon whom they were to throw the whole of the work, and to whom they were to refer everything. The sub-committee could be drawn from the whole body, and if they had a hundred members it was possible that the whole number might be serving on the various committees.

Mr. WILDING thought there was an idea that this committee was to be a technical committee, and that the sub-committees should be technical also. There ought to be rather a division of commercial interests, and they should divest themselves entirely of the technical idea.

Mr. GARCKE reminded the meeting that a small committee worked better than a large one.

Mr. H. S. PRICE suggested that the committee should be composed of not less than ten members.

Mr. RAWSON suggested twelve, and after some further conversation the twelve was accepted, and the motion was then carried unanimously.

The meeting then proceeded by ballot to elect the twelve members, the CHAIRMAN stating that Mr. Murray had informed him that they could vote for any gentleman in the trade, subject to his subsequently qualifying as a member of the London Chamber of Commerce.

The papers having been collected,

The CHAIRMAN announced that the following eleven gentlemen had been elected members—Price, Garcke, Webber, Gatehouse, Rawson, Wharton, Trotter, Siemens, Flood-Page, Callender and Crompton. Messrs. Immisch, Gray and Courtenay had tied for the 12th place—what was to be done? Would the meeting choose between these gentlemen by show of hands, or would they add those three gentlemen to the Committee?

It was decided to adopt the latter suggestion, and a vote of thanks to the Chairman having been carried unanimously, the proceedings terminated.

COMPANIES' MEETINGS & REPORTS.

Globe Telegraph and Trust Company.

The fifteenth ordinary general meeting of this company was held last Friday at Winchester House, Old Broad-street, under the presidency of Sir John Pender, K.C.M.G.

The SECRETARY (Mr. W. Payton) having read the notice convening the meeting and the minutes of the last meeting, the report of the Directors was taken as read.

The CHAIRMAN: Before asking you to approve of the resolution which I will read, I will make a few remarks as usual on the working during the past year of the different concerns in which we are interested. The resolution is—

"That the report and accounts for the year ended July 18th, 1888, submitted to this meeting be and they are hereby received and adopted, and that a dividend be now declared payable on and after this day of 3s. per share on the Preference shares (less income-tax), and of 3s. per share on the Ordinary shares, income-tax having already been deducted, making, with previous payments, a total dividend for the year of 6 per cent. on the Preference shares (less income-tax), and of 3½ per cent. net on the Ordinary shares."

Gentlemen, when I last had the pleasure of addressing you our prospects were not bright, and the surroundings were rather gloomy. The Atlantic system was being worked at a very low rate; and the Eastern and Eastern Extension systems, in which we are largely interested, were just feeling the effects of the reduction that had been made at the Berlin Conference. We then, I believe, paid you the lowest dividend that the Company has ever paid. To-day I am glad to say that things look brighter. What was obliged to be given up at the Berlin Conference has been in a great measure recouped, and we have also now the prospect of seeing an increase in the rate upon the Atlantic systems. I may also say that the prospects of the other investments are all encouraging. The Eastern system is doing well; and the South African system, in which the Eastern Company are the principal proprietors, is doing remarkably well. The Eastern Extension Company is also doing well. In all those companies we are very largely interested indeed. We are also interested now to some extent—and very shortly we may be interested to a larger extent—in the Western and Brazilian Company. The Brazilian Company's system we are largely interested in; and that is doing well. The Western and Brazilian Company is emerging from a state of depression, and I think is taking up a worthy position among the other telegraph systems which now encircle the world. Therefore, upon the whole, our prospects are very much brighter than when I last had the pleasure of addressing you. But the first question—the one which interests you more immediately—is that of the dividend. It is so far satisfactory that we now pay £3. 10s. per cent. for this year, as against £2. 7s. 6d. per cent. for last year. I have generally on these occasions brought before you our position as to dividends from year to year, so that you may contrast them with the dividends paid by the different submarine telegraph companies, and in order to give you some idea of the dividends of the Globe Company as a trust company in which you will find the averages. Taking our dividends from the beginning, including this year—that is, extending over a period of fifteen years—we have always paid our Preference dividend; and our highest dividend on the Ordinary shares has been 5½ per cent., and the lowest, paid last year, has been 2⅜ per cent. All the dividends combined form an average of 6 per cent. on the Preference shares, and of £4. 4s. 8d. per cent. on the Ordinary shares; or, taken together, on our combined shares the average dividend paid by us has been £5 2s. 4d. per cent. or, say, 5⅛ per cent. This is a point of interest to us, as showing that the system of averages which this Company set up for telegraph shares and stocks has, on the whole, been successful, and that whilst a shareholder who, say, has brought in his Anglo-American shares at par has reason to be glad, the shareholder who brought in Eastern, Eastern Extension, or Indo-European shares has had no reason to regret it, because his position meanwhile has been made secure. Those who brought in Anglo-American shares are getting double the dividend they would have received had they remained simply in

Digitized by Google

direct connection with that Company. If we take the last four years we find that the Eastern Company have contributed £53,000 in 1885, £53,000 in 1886, £48,448 in 1887, and £53,000 in 1888. You will observe that 1887 was the period when we were working at and feeling the reduced rates imposed at the Berlin Telegraph Conference. The Eastern Extension Company gave us £39,176 in 1885, and £39,176 in 1886. It is very remarkable how much one year is like another for a certain time, and then we have bounds, and next little deficiencies. In 1887 the Eastern Extension Company gave us £33,000, and in 1888 £36,000. This has enabled us to maintain our dividends on our Ordinary shares, but, as you are aware, during the last two years the Anglo-American Company has been paying next to no dividend at all; and as our investment in that company is very large the return it makes us very materially affects our dividend. Therefore, the prospect of an increased tariff, which I believe is now settled, to come into operation about the 1st of September, when it is proposed that the rate shall be raised from 6d. to 1s., is of considerable importance in its bearing on us. If that 1s. rate gives the companies anything like the increased traffic brought about by the 6d. tariff—if that traffic is maintained—then I expect we shall be very beneficially affected. I may mention that every additional 1 per cent. paid on the Anglo-American Stock means 1s. 6d. a share on our Ordinary shares—that is, ¾ per cent. additional, so that if the Anglo-American Company pay what we expect it will pay next year it will give us practically 1 per cent. additional dividend if all the other companies in which we are interested should be in precisely the same position as they are in to-day, but let us also hope that there will be progress in those other companies also. I therefore look forward to the time, not very far distant, when we may resume something like the respectable dividends we paid in the earlier part of the Globe Company's career. Since I had the pleasure of addressing you last the German Government have taken over the Channel cable, and we who have a large interest in that concern are now about to be paid off. I expect that we shall be paid off at the end of this year, and at a very considerable premium; and I hope that with the premium and the good investment we shall make of the money handed to us we shall not get in the future a smaller amount of interest on that particular portion of our capital than we have been obtaining in the past. As I have said, we are now interested to some extent in the prosperity of the Western and Brazilian Company, and we believe that that undertaking will prosper. The general aspect of submarine telegraph affairs at the present moment may be regarded as favourable. The war of rates has been a very disastrous war. I am one of those who are now managing in connection with that matter, and I never believe in throwing away money if that can be avoided. Mr. Mackay and Mr. Bennett, who did not know very much about telegraphy, thought a great deal of money was to be gained, and a good deal of prestige too, if they established a cable at low rates. They thought they were going to be national benefactors; but it does not require long to convince a man that it is not very profitable business to be engaged in when he finds he is putting his hand into his pocket instead of putting money there as a return for his investment. I think that that is being realised now, and as it takes a long time to bring about a combination when people have suffered I think we shall have a quieter time in the submarine telegraph system. During that quieter time I hope we shall have such an amount of progress as will materially tell on the interests of the Globe Company. With these remarks, and congratulating you upon the improvement in your position which I have forshadowed, I beg to move the adoption of the resolution which I have read.

The Marquis of TWEEDDALE seconded the motion.

After remarks made and questions put by the following gentlemen, viz., Dr. Griffiths, LL.D.; Mr. Weatherley, Mr. Odell, the Rev. J. J. Heaver—all shareholders of the Company—the resolution was put from the chair and carried unanimously.

On the motion of the CHAIRMAN, seconded by Sir JAMES ANDERSON, the Marquis of Tweeddale was re-elected a Director of the Company, as was also Mr. Henry Daniel Gooch, on the motion of the CHAIRMAN, seconded by Dr. GRIFFITHS.

Mr. NEWTON then proposed, and Dr. GRIFFITHS seconded, the re-election as auditors of Mr. John George Griffiths, F.C.A. (of the firm of Messrs. Deloitte, Dever, Griffiths and Co.), and of Mr. Wm. Griffith, B.A.

Mr. WM. GRIFFITH returned thanks, and assured the shareholders that they were in a sound state. The securities were all safe, and the accounts were well vouched for. He hoped the picture drawn of the future success would be realised. They were in a condition to take advantage of it, and he hoped they would be able to do so.

A vote of thanks to the Chairman and Directors was then passed.

The CHAIRMAN: I beg to thank you on behalf of my colleagues and myself, and notwithstanding the remarks that are made to throw doubt upon us and to cut us down as much as possible, I can say that your interests are in very safe hands. I am glad to say, further, that as far as any movement against the Directors is concerned, that does not arise from the body of the shareholders, who are loyal and true, and who believe in the men acting for them. I beg to thank you.

The proceedings then terminated.

The Submarine Telegraph Company.

The half-yearly general meeting of this Company was held on Tuesday, at the offices, 2, Throgmorton-avenue, London-wall, E.C., Sir Julian Goldsmid, Bart., M.P., in the chair.

Mr. S. M. CLARE (the secretary) read the notice convening the meeting, and the following is the report of the Directors, which was taken as read:—

The joint earnings of the two companies for the six months ended 30th June, 1888, amounted to £67,397. 18s. 9d., and the working expenses to £27,788. 1s. 9½d. The joint earnings are £2,663. 10s. 8d. more, and the working expenses £521. 4s. 5½d. less than the corresponding period of 1887. The result of the business for the half-year enables the Directors to add, as usual, 15 per cent. of this Company's proportion of the receipts to the reserve fund, to recommend a dividend at the rate of 13½ per cent. per annum, and to carry a balance of £261. 4s. 7d. to next account. The dividend paid for the half-year ended 30th June, 1887, was at the rate of 12 per cent. The number of messages transmitted in the six months ended 30th June, 1888, was 1,717,311, containing 19,073,919 words, against 1,618,634 messages in 1887, containing 17,901,009 words. All the Company's cables, as well as those worked by the Company, are in good working order. The Company's steamer "Lady Carmichael" has been thoroughly overhauled in the course of the half year at a cost of £907. 14s 9d., of which £500 has been charged in the annexed accounts, and the balance will be charged against the revenue of the next half year. The steamer is now in excellent condition, both as to her hull and general machinery, and has been surveyed by Lloyd's surveyors, who have classified her as 90 A1, *i.e.*, as a vessel of the first class. The negotiations between Her Majes y's Government and the Board, referred to in the last report, have been continued during the half year, and are now on the point of completion. As soon as an agreement has been finally arrived at the Directors will forthwith lay it before the proprietors for their approval.

The CHAIRMAN said: It now devolves upon me to move the adoption of the report and statement of accounts, and the observations I have to make to-day are very short and very simple. You will see that there has been a fair increase in the traffic during the six months which are now under review. The number of words is given in the report. The average length of the messages is not given; I dare say that that is a matter of interest to many people. I find that last year during the same period of six months the average length of the messages was 11·06; during the period now under review it was 11·11, showing a very slight improvement in the length of the messages. I have often told you in former years, when we complained of the diminution in the number of words in the messages, that I thought we must come to a termination of that reduction before long, and when I was asked to fix a figure at which it would terminate I said I should not imagine it would go below 11. It has gone below 11 on one or two occasions, but it appears to me that that is the average. It is a subject of only passing interest to us now. Much to our regret, as you know, our concession will terminate very shortly. I mentioned to you on a previous occasion, not so very long ago, we had great hopes that the concession given to us by the French Government would be renewed, and if it had not been for the very strong opinion entertained by the English Government on this subject I believe that would have been the case; but, like sensible men, a decision having been come to, we thought it in the interest of the shareholders of this Company to make the best of it, and, consequently, ever since we have all been in active negotiation with our Government and the French Government on the subject of taking over the property of this Company at the termination of the concession. Mr. Brand told you last winter, when he was in the chair, that those negotiations were progressing; they have continued ever since. I have been in constant communication with various members of the Government upon the points that have been raised, and upon most of them we have come to an arrangement, but there are still some which depend partly upon the English and partly upon the French Government, which are not finally concluded, and consequently I am not able to place before you to-day any result of our negotiations. Of course, you are aware we can only provisionally agree to anything which we may consider desirable, and that it will have to be submitted to the shareholders for their sanction and approval. But as ever since I have been on the Board, and I believe ever since any gentleman present has been on the Board, the shareholders have always shown the greatest confidence in the Board, I think you will now rely on the fact that we are doing our very best in the interest of the Company itself. Gentlemen, I do not know that it is necessary for me to say more than that. I would just add that we have maintained our cables and our ship—in fact, all the property connected with our business—in the best possible condition, and I believe there is no telegraph company in the world that has a better plant than we have at the present time. I think, therefore, that if our property is purchased it will be a very valuable property, with a very large income attached to it, and that the persons, of course, who will gain will be the Governments of the countries who obtain it. Gentlemen, I think that is all I have to say. I beg to move the adoption of the report and accounts.

The Hon. ASHLEY PONSONBY seconded the motion.

Mr. SODEN said that on the last occasion he made some observations, and he would not pretend to go through what he then said. He did not wish to say a word that would in any way hamper the Board, in whom the shareholders had rightly the utmost confidence, but he could not help saying that all telegraph companies carrying on business in this country to parts beyond the United Kingdom were in one sense certainly in exactly the same position as this Company—they all held by the license of the Crown the use of the foreshore; and if the Government considered it a wise policy to buy up the business and trade of submarine telegraphs, they ought to pay what was fair and just. This was not the place to discuss the wisdom of that policy, but it seemed to him that it was the interest of every shareholder in this Company to interest every shareholder in every other submarine company starting from these shores, because they were all more or less in the hands of the Government. The Government might any day arbitrarily, or for good reasons, give notice to revoke the license for the use of the foreshore, and away would go a business built up by a vast expenditure of capital. Whatever was done on this occasion would be a precedent in the future, and they ought to bear in mind that most of the companies did business

Digitized by Google

with our colonies, and it seemed to him if this was carried it was not at all improbable a somewhat similar policy would be adopted with regard to submarine telegraphs to our colonies.

The CHAIRMAN replied that he did not understand that the hon. proprietor had made any objections to the remarks he had made, or to the course that the directors had adopted. He could assure the hon. proprietor that he and his colleagues had not forgotten any argument which could be used, or to enlist any interest which they possibly could, and which they thought might be of special value, but the difficulties with which they were surrounded arose from the fact that it was not only the English Government with whom they had to deal and satisfy, but they had to treat with the French and one or two other Governments, who were intimately concerned in this matter, and consequently a proposal which might entirely satisfy one would not satisfy another. It was impossible to foresee every eventuality which might occur, and he could assure the shareholders that the Directors had done their best in the interest of the shareholders. If they had not met the success they desired it was not owing to any fault of their own, but owing to affairs over which they had no control.

The motion was then put to the meeting and carried unanimously.

A dividend at the rate of 13½ per cent. per annum, less income-tax, was then declared payable on and after the 1st September next.

The Hon. Ashley Ponsonby and the Hon. H. B. Brand, the retiring Directors, were re-elected, and Mr. William R. Cole and Sir Thomas Dakin, the retiring auditors, were re-appointed.

A vote of thanks to the Chairman and Directors then closed the meeting.

The Northern District Telephone Company (Limited).

At the sixth annual meeting of the above Company, held at the offices, Arcade-chambers, Sunderland, Mr. R. T. Wilkinson presiding, the report of the Directors was read for the year ending 31st of December, 1887. The following is a summary :—

Capital Expenditure.—The capital expenditure for the year has been £14,657. 15s. 2d., which, added to previous amount of £31,854. 5s. 6d., shows a total of £46,512. 0s. 8d. expended in the Company's district.

Revenue and Expenditure.—The revenue accounts show that the receipts of the Company from all sources, attributable to the year, have been £6,585. 16s. 1d., as against £4,277. 7s. 10d. for 1886, or an increase of £2,308. 8s. 3d. ; and the expenditure has been £2,858. 14s. 1d., as against £2,041. 10s. 9d. for 1886, an increase of £817. 3s. 4d.

Progress of Business.—The Company are continuing to make considerable progress in the development of their system. The number of subscribers to the exchanges have increased from 438 on 31st December, 1886 (representing a total rental of £4,114. 3s.), to 562 subscribers on 31st December, 1887 (representing a total rental of £7,277. 19s. 4d.). Exchanges have been opened at Blyth, Bishop Auckland, and Seaham, and are now working satisfactorily. The Company have now in all thirteen exchanges in full working order. Considerable additions have been made to the trunk wires connecting the whole of the Company's system together. The private line business of the Company continues to increase, the rentals from this source being £1,430. 15s. 1d., as against £1,237. 8s. 4d. last year, and the Directors still anticipate a very large increase during the present year. The Company have 150 private lines erected in the various towns of their district, and the Directors are glad to state that the use of the trunk wires between the various towns is very rapidly increasing, the amount received for occasional messages alone being £511. 4s. 9d., as against £105. 3s. 6d. for the year ended 31st December, 1886. The continued development of the Company's business is further evinced by the fact that of the total amount of the rentals for the year 1887 (£7,817. 12s. 9d.), the large proportion of £3,217. 6s. 10d. is carried forward to 1888, against £2,038. 0s. 2d., brought forward from 1886.

Dividend.—The balance of net revenue as shown by the balance-sheet is £2,392. 5s. 11d., of which £2,333. 14s. is absorbed by the payment of the dividend of 6 per cent. upon the paid-up Preference capital, leaving a balance of £58. 11s. 11d. carried forward. The progress of the business for the present year has, so far, been such as to lead the Directors to hope that they may be able to recommend at their next annual meeting a dividend upon the Ordinary shares of the Company.

The CHAIRMAN, in moving the adoption of the report, congratulated the shareholders on the great progress made by the Company during the past year, notwithstanding the strong competition of the Post Office. With respect to this competition, the Post Office have lately abandoned their exchange in Plymouth, leaving the ground to a private company, the Western Counties Telephone Company (Limited), and he had little doubt that it would be to the interest of the Post Office revenue, and also the commercial population, if the same policy was carried out in this district. The increase in the revenue over 1886 amounted to £2,303. 3s. 3d., and he was glad to say the current year would show a much better result. For the first six months of the present year the revenue from subscribers alone had increased by no less a sum than £1,674. 13s. 7d. The large increase in the calls also proved that the public had appreciated the policy of the Directors in reducing the charge for local calls to one penny, and in opening call offices where they found there was a demand. The charge made for conversations by this Company was, he believed, at a less rate than any other telephone system in existence, but the public at large had not as yet realised the fact that for sixpence they could converse for three minutes with their friends between any of the following towns, namely, Sunderland, Newcastle, North or South Shields, Durham, Bishop Auckland, the Hartlepools, Stockton, Middlesbrough, Darlington, Blyth, or Seaham, whereby they could ask and receive a reply for half the price of the lowest charge for telegraphic communication, and for the sum of one penny they could speak to their friends or order their goods from their tradesmen. The local and trunk calls had increased 71 per cent. over the preceding year. The Chairman regretted to say that as regards Newcastle the Company had not made the progress they expected, partly owing to the competition of the Post Office, also to other minor difficulties ; but he was glad to be able to report that the United Telephone Company had at last obtained an agreement with the City Corporation for them, which would admit of the application of cheap rates of subscription and of the rapid erection of lines. The amount shown in the balance sheet as being in suspense is so treated by permission of the United Company, who desired to have a legal decision concerning various items of the agreement with the District Companies before calling upon us to admit the liability. The matter, which arose in the case of the Lancashire Company, has recently been arranged, and the similar items in our accounts will therefore now be settled probably with some concessions on the part of the United Company, who have always hitherto met us in a generous spirit, and with whom we have always been on the best of terms.

Mr. J. B. MORGAN, Managing Director of the United Company, congratulated the meeting on the progress of the Northern Company, and promised to use his best endeavours to arrange all matters not yet settled between the Company and the United Company. He then proceeded to explain the progress of the negotiations for the amalgamation of the different companies, and said that as soon as these were completed the district would be put in trunk communication with London, Liverpool, Bristol, South Wales, Birmingham, and the Midland districts on the south and west, and to Scotland on the north.

It was unanimously decided, after some discussion, to accept the principle of the amalgamation, leaving the details for other arrangement.

On the motion of the CHAIRMAN, seconded by the VICE-CHAIRMAN, a dividend of 6 per cent. was declared on the Preference Shares.

Mr. R. M. Hudson, jun., was re-elected a Director on the motion of the CHAIRMAN, seconded by Mr. MORGAN, and Mr. Smyrke was also re-elected auditor.

The meeting was then resolved into an extraordinary general meeting, and the following resolution was moved and carried ;—

"*That the Articles of Association be altered as follows :—*

"*(a) The following Article shall be substituted for Article 67a, namely :—' They may borrow any sum or sums of money on such security and terms as to interest or otherwise as they may deem fit, and may secure the same by mortgage or other debentures or by bonds or other securities, or by any mortgage or charge of or upon the whole or any part of any property, funds, assets, or effects of the Company or its uncalled capital ; but so that not more than £25,000 be owing at any time without the consent of a general meeting, and provided that no part of the said sum of £25,000 shall be borrowed without the consent of the United Telephone Company (Limited), and no borrowed money shall, without the like consent, carry interest at a higher rate than 6 per cent. per annum.'*

"*(b) In Article 87, the word 'and' coming after the word 'agencies' shall be omitted, and the words 'trunk lines and new business' shall be inserted after the word 'branches.' The clause as amended shall apply as from the formation of the Company.*"

A vote of thanks to the Chairman having been passed unanimously, the meeting terminated.

South-Eastern (Brush) Electric Light and Power Company (Limited).

An extraordinary general meeting of this Company was held on the 30th ult., at the Guildhall Tavern, Gresham-street, at which, the notice intimated, the following resolutions would be proposed :—

"*1. That the accounts and report presented by the liquidator (audited and approved by four of the principal shareholders) as to the manner in which the winding up has been conducted and the property of the Company disposed of be received and adopted, and that the liquidator be authorised to distribute the balance of cash in hand as proposed in the said accounts.*"

"*2. That the liquidator be authorised to destroy all books and papers of this Company, and of, or relating to, this liquidation at the expiration of three months from this date.*"

"*3. That the liquidator do forthwith, in accordance with Section 143 of the Companies Act, 1862, report to the Registrar of Joint Stock Companies that the affairs of this Company are fully wound up, and that the final meeting has been held.*"

The chair was taken by the liquidator, Mr. W. H. Pannell, F.C.A., from whose report the following passages are extracted :—" When my appointment was completed by the confirmatory resolution of the Company, on the 13th August, 1885, the Company held a large nominal value of shares and debentures of the Consolidated Electric Company (Limited). These now form the first assets in this balance-sheet ; but as neither of them were then of any marketable value, and the Consolidated Company was shortly afterwards compelled to liquidate, and proved to be quite insolvent, I have been unable to derive any benefit from them, and, together with other nominal assets, they form a large item at the head of the deficit column. The next and most important item then appearing in the balance-sheet is the Company's property at Colchester. The position as to this I have already explained in my circular of the 14th May, 1887, and I will therefore only recall that in the unique position in which I was placed with respect to this property, and in view of the serious statutory liabilities of the Company under its license, and of the not only expensive but (in addition to the liability to an injunction in Chancery to restrain such a course) the positively ruinous consequences of a cessation of the light, which would probably have entailed, in lieu of the call of 2s. 3d., with which I have now succeeded in closing the matter, a loss of the whole remaining capital of 6s. 6d. per share, I was compelled to continue the Company's contracts and works there until

Digitized by Google

I could dispose of the whole, with the licence, as a going concern, which was not until nearly a year after the liquidation. So that in addition to the loss shown on sale of the property, there was a further loss of nearly £500 from carrying on the business during this period, which, added to the serious but necessary legal expenses in obtaining the sanctions and consents from the Board of Trade, the Chancery Division of the High Court, the local authority, and the numerous private parties concerned (required for the purpose of releasing the Company from the statutory liabilities already referred to), and taking account of the deduction from the price obtained, by reason of the indemnity against claims of the consumers (which have since been paid in cash by the purchasers), and of the difficulty of collecting a portion even of the disputed debts of the consumers for light and goods already supplied, reduced the net proceeds of the realisation, as shown in detail in the accompanying cash account, to the small sum of £116. . . . I have in hand a balance of £913. 18s. 1d. The final account explains the manner in which I propose to distribute this balance, and the ultimate position in which the capital account will then stand; leaving unused assets of 4s. 3½d. per share—equal to £3,959. 18s. 5d.—and bears a certificate by some of the leading shareholders of the Company representing between them the great bulk of the capital issued." The account showing the proposed distribution of the balance in hand stated that the total loss had been £45,953. It was proposed to distribute by way of dividend as return of capital 8s. 7d. a share on 400 fully-paid shares (£171. 13s. 4d.), and ½d. a share on 17,654 Ordinary shares (£36. 15s. 7d.).

The LIQUIDATOR stated that he had called the meeting in conformity with the Act of Parliament. If any gentleman had any question to ask, now was the time for doing so. He then put the first resolution (moved by Mr. C. H. Stewart and seconded by Mr. A. Leland Noel).

The LIQUIDATOR, in answer to Mr. Brooker, said that the return on the Ordinary shares was ½d. a share, and the return on the fully paid shares would absorb the balance.

Mr. BROOKER said that the fully paid shares were not entitled to anything. It was a most illegal thing to take over the Consolidated Company.

The LIQUIDATOR said that that had been done by the Directors before he had any connection with the Company. The claim of the holders of the 400 fully paid shares had been £2. 16s. 6d. a share, but he successfully reduced that by treating it as a claim on 800 £2. 10s. shares instead of 400 £5 shares.

Mr. BROOKER desired that the books might not be destroyed. The shareholders would see if they could not prosecute the promoters, Directors, and others who had been connected with the Company.

The LIQUIDATOR stated that he was not connected with either the South-Eastern or the Provincial Company until he became liquidator. He then put the motion and it was carried. The second resolution was then proposed.

Mr. JOHN EVANS said it was of no use going on and spending every shilling which might otherwise be available for the shareholders.

Mr. BROOKER: It was a swindle.

Mr. EVANS: Then I am in it. I am one of the swindled. It appears to me that the liquidator has done all he could for us. Let us bring the matter to an end as quickly as possible, and I hope that the books will be destroyed.

Mr. BROOKER: That is what the Directors want.

The LIQUIDATOR put the resolution, which was carried. He then put the third resolution, which was also carried, and the meeting terminated.

Provincial (Brush) Electric Light and Power Company (Limited).

An extraordinary general meeting of this Company was held subsequently, Mr. Pannell again presiding, the resolutions submitted being the same as at the meeting of the South-Eastern Company.

The report of the liquidator stated:—"It will be remembered that when my appointment was completed by the confirmatory resolution of the Company, on the 26th June, 1885, the Company held a large nominal value of shares and debentures of the Consolidated Electric Company (Limited). These now form the first assets in this balance sheet, but as neither of them were of any marketable value, and the Consolidated Company was shortly afterwards compelled to liquidate, and proved to be quite insolvent, I have been unable to derive any benefit from them, and, together with other nominal assets, they form a large item at the head of the deficiency column. The assets to be realised were thus reduced to some book debts (the chief of which were disputed), the stock on hand (at cost, not valuation), the office furniture and fittings, and a small amount in cash and stamps. The Liquidation Account starts with the deficiency on realisation of the assets already mentioned. The next item is the further claims paid. Here again it will be seen that, though in addition to a large amount of time and trouble, I have incurred law costs to the extent of £78 in resisting these claims, principally a claim of the Consolidated Company (ultimately admitted under the orders of the Court at £1,800), for further advances on the debentures above referred to, and on current account, this amount is very far more than covered by the large reduction I succeeded in making in such claims. Adding to the admitted claims the general costs of liquidation, and taking, on the other hand, the nominal surplus brought from the balance-sheet, and the further capital collected, I have a balance in hand of £618. 14s. 6d. . . . . I had thus net proceeds of £692 only, and as I had on the other hand to meet claims for £2,267, it became necessary to obtain further capital from the shareholders. This entailed law costs to the extent of £102, but it should be noticed that while this is more than covered by the £107 of arrears collected, it was expended in recovering, not only this amount, but also a very large proportion of the further call made by me, which, upon a list of over 800 contributories, could not otherwise have been obtained. The concluding account explains the manner in which I propose to distribute the balance of cash in hand, and the ultimate position in which the capital account will then stand, leaving unused assets of 2s. 9½d. per share, equal to £2,498. 17s. 3d., and bears a

certificate by some of the leading shareholders of the Company, representing between them the great bulk of the capital issued. The balance available for distribution by way of dividend, as return of capital to the shareholders, was, at the rate of 3½d. a share, £248. 19s. 9d. The total loss of capital had been £51,096."

Mr. C. H. STEWART moved the first resolution. He said he quite sympathised with Mr. Brooker in his observations as to the Directors and the management of both companies. The liquidator had, however, attended well to the interests of the shareholders. If he had not done so they might have had more calls to pay instead of receiving a small return. In that case their position would have been even worse than it was.

The motion was seconded and carried with one dissentient—Mr. Brooker.

The second resolution as to destroying the books, &c., in three months, was then proposed.

Mr. BROOKER: Alter that to 12 months.

The LIQUIDATOR said he could not do so, and the feeling of the meeting was evidently with him.

Mr. BROOKER: Are you bound to three months?

The LIQUIDATOR replied in the negative, but added that by operation of law, after that meeting the Company would be dissolved in three months. The liquidation had been going on for some time.

Mr. BROOKER moved an amendment that the books be not destroyed for 12 months, so as to give the shareholders time to consider what steps they should take.

Mr. EVANS: You have had three years.

Mr. BROOKER: We ought not to let these men off scot free. If I were to come to your office you would not let me overhaul the books as I like?

The LIQUIDATOR: Certainly, I will.

Mr. BROOKER: Then I will come.

The LIQUIDATOR said that the amendment was not seconded, and put the resolution, which was agreed to.

Mr. NOEL next proposed, and Mr. STEWART seconded, the third resolution, which was also agreed to, Mr. BROOKER dissenting.

A SHAREHOLDER: When is it proposed to pay this?

The LIQUIDATOR: At once.

Mr. STEWART proposed a vote of thanks to the liquidator for the manner in which he had conducted the winding up and brought it to a conclusion. There was no doubt that it had been a difficult and intricate matter to deal with. With the Consolidated Company neither the South-Eastern nor the Provincial Company had had anything to do, except that they had been drawn upon *ad lib.* for the benefit of the Consolidated Company. There was no doubt that the inception of the two companies and the working of them had been a stain upon the commercial morality of the city. Seeing the difficulties that had had to be contended against, he thought the liquidator had got over them in a masterly manner. He (Mr. Stewart) was a severe sufferer by both companies.

Mr. BROOKER seconded the motion, which was carried unanimously.

The LIQUIDATOR, in acknowledging the vote, said that the liquidation of the South-Eastern Company had been unique, because it was the first case where a liquidator had been called upon to liquidate an electric light company having an installation lighting a town, and the various authorities he had had to deal with had caused the solicitor and himself a good deal of trouble. However, the liquidation had resulted so far satisfactorily that the shareholders had not been called upon to contribute to the full amount of their shares.

The proceedings then terminated.

National Telephone Company (Limited).

Report of the Directors for the year ended 30th June, 1888, to be presented to the shareholders at the eighth annual ordinary general meeting of the Company, to be held at the Offices of the Company, 162A, Queen Victoria-street, London, E.C., on Saturday, 4th August, at 12 o'clock:—

Capital Expenditure.—The capital expenditure for the year has been £43.854. 8s. 6d., against £36,718. 12s. 1d. in the previous year.

Revenue.—The gross revenue allocated to the past year is £99,119s. 2s. 2d., against £85,073. 6s. 1d. allocated to the previous year, and the amount carried forward to next year is £58,495. 18s. 4d., against £49,525. 15s. 8d. carried forward last year. The annual rentals on the 30th June reached £106,572. 12s. 7d., against £90,537. 2s. 4d. at the corresponding date of the previous year, showing an increase of £16,035. 10s. 3d. There is also a revenue derived from fee messages, at the rate of £3,000 a year, against £1,800 last year, making the total gross revenue reached on the

30th June £109,572. 12s. 7d., and giving an increase of £17,235. 10s. 3d. over the total of last year.

Dividends.—After providing for the accrued interest on the debentures, the dividend of 6 per cent. on the First Preference Shares, the dividend of 6 per cent. on the amount of Second Preference capital paid up, and after having paid an interim dividend for the first half of the year, at the rate of 4 per cent. per annum, on the Ordinary capital, there remains a balance of profit amounting to £17,003. 5s. 1d. Out of this the Directors propose to allot a further sum of £11,250 to the payment of a dividend upon the Ordinary capital for the second half of the year, at the rate of 5 per cent. per annum, and besides placing £2,500 to the reserve fund, to carry forward £3,253. 5s. 1d. Out of the amount carried forward a sum will be required towards the adjustment of long-standing claims between the United Telephone Company and this Company, now in process of being satisfactorily settled by mutual concession.

Trunk Wires.—The Company has increased its trunk system, so that it has now 842 miles of trunk pole lines connecting towns with each other, carrying 2,509 miles of wire, against 643 miles of pole lines carrying 1,919 miles of wire at the same time last year.

New Exchanges.—The Company has 117 telephonic exchanges with 8,056 lines. The lines of the private wire renters number 1,268, making the total number of exchange and private lines 9,324. The increase of exchanges is 26 and of exchange and private lines, 1,470.

Retiring Directors.—The retiring Directors are Messrs. John Bruce, Edinburgh, and Jeremiah Garnett, Manchester, who, being eligible, offer themselves for re-election.

Retiring Auditors.—The auditors, Messrs. Quilter, Welton and Co., also retire, and are eligible for re-election.

NEW COMPANIES REGISTERED.

CROMPTON AND COMPANY (LIMITED).—Registered by Ashurst, Morris, Crisp and Co., 6, Old Jewry, E.C., with a capital of £140,000, in £5 shares. Object, to adopt and carry into effect an agreement dated July 16, 1888, and made between R. E. Crompton and Co. of the one part and Francis R. Reeves, on behalf of the company, of the other, for the acquisition by the company of the business, goodwill, machinery, privileges and other property of Messrs. R. E. Crompton and Co.; to acquire any additional letters patent relating to inventions for the production or supply of heat, light or power by means of electricity, magnetism, or any other agent, or any inventions of a like character, and to take and work any license or business in connection with such inventions. The first subscribers are:—

Offices—**WINCHESTER HOUSE, OLD BROAD STREET, LONDON, E.C.**

The principal objects of the Corporation are:—

1. Performing the duties of Trustee, Executor and Administrator.
2. The Insurance of Bonds, Shares and all other Securities lodged with the Corporation against risks of all kinds.
3. The Issue of Warrants and Certificates against Securities deposited, and making and procuring advances on such Warrants.

The Office of Trustee or Executor is to private persons usually a thankless post, involving much anxiety, time and money, and frequently leads to serious actual loss; whilst death, illness and change of residence necessitate frequent fresh appointments, and consequent expense to the parties interested. The Corporation undertakes all the duties of Executor, Trustee or Administrator for reasonable remuneration proportioned to the work and responsibility in each case.

The Corporation insures existing Trustees and Executors against all risks attending those positions, where the business is conducted by the Solicitors to their Trusts under the supervision of the Corporation, it not being the desire of the Corporation to interfere in any way with the duties of the family solicitor.

The Corporation acts as Trustees for the Debenture Holders in Public Companies.

For terms, &c., application should be made to the General Manager at the Company's Office.

GEORGE PEARSON, *General Manager and Secretary.*

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL SCIENCE, INDUSTRY AND ENGINEERING.

No. 534.—Vol. XXI. FRIDAY, AUGUST 10, 1888. Price 4d.

NOTES.

The Philosophical Magazine for August contains a highly interesting and important Paper by Dr. Oliver Lodge "On the Theory of Lightning Conductors," in which the author deals with the results of some of the experiments which he lately exhibited before the Society of Arts from a mathematical standpoint. Amongst other striking conclusions he is able to estimate the order of magnitude of the frequency of the oscillations of a lightning flash at about one million per second. The results which follow from this excessive rate of alternation are both curious and instructive. The author hesitates to express a final opinion whether it is not, after all, a better plan to insulate lightning conductors from the buildings to which they are attached. We present a tolerably full abstract of the Paper further on, but must refer our readers to the original article for the complete mathematical reasoning.

Prof. Elihu Thomson (U.S.A.) states that he has observed as many as six lightning-flashes very quickly following each other along the same path. He kept his head rapidly wagging during a thunderstorm, and his eyes fixed in one direction, which is a well-known method of observing discontinuity of illumination.

The half-yearly dividend of the London Street Tramways Company has fallen from 8½ to 4 per cent. per annum, and consequently the directors had to face a stormy meeting on Wednesday. The Chairman explained that the fall was largely due to the high price of forage and excessive mortality amongst their horses. The price of forage is not at all likely to come down, but nevertheless the shareholders have at hand a very simple and perfectly trustworthy means of raising their dividend. We have no doubt whatever that the line could be worked by electric traction at a cost not exceeding 5d. per car mile. The shareholders can easily form an idea as to the dividend which this figure would imply, and since there are now nearly 100 tramway lines worked by electricity in the United States alone, there need be no hesitation on the score of the supposed experimental character of the undertaking.

Our esteemed contemporary, the *Electrical Review*, whilst sharing our views with regard to the impracticability of the proposals for working the Underground Railway by accumulators, thinks that we have considerably over-estimated the weight of the cells. Our contemporary does not advance any calculation in support of this criticism. The figures we gave a fortnight ago were, however, based upon actual estimates separately prepared by two of the leading manufacturers of accumulators in this country, in connection with a scheme for working an electric tram or railway line in Spain. The estimate was in each case very nearly equivalent to a dead weight of 7cwt. for each horse-power electrical, with a discharge of two hours. This figure is, of course, very much in excess of that corresponding to the normal type of cells intended for lighting purposes, and if the question of duration is not to be considered, no doubt it can be much diminished, even when the cells are to be used for electric traction. The Spanish railway, by the bye, is *not* to be worked by accumulators. From the statements which we published as long ago as April 27 (p. 705) it may be conjectured that the projectors of the present scheme consider the life of the cells to be of secondary importance, hoping later on to induce the Railway Company to adopt a method of working better calculated for a permanent success. If this be the true explanation of the present state of affairs we can only express bewilderment at the short-sighted character of the policy adopted. When the Metropolitan Railway Company have once got the electric locomotive upon their lines it can hardly be supposed that they will neglect the question of the cost of working, or that in this connection they will overlook the importance of the item of depreciation. And if the direct system of working be the method finally aimed at by the Electric Traction Company, it is still more difficult to understand how its adoption is to be facilitated by first presenting an experiment which at the very best must be both costly and inconclusive. In this relation, however, Mr. Evershed's article on "Electric Traction," which appears in another column, may be studied with advantage.

By far the most valuable contribution we have yet met with on the subject of technical education is from the pen of Dr. Crichton-Browne in this month's *National Review*. If anyone suspect the writer of prejudice because of the strong line which he took up some time ago against over-pressure in elementary schools, their misgivings will all disappear on perusal of this article. He gives physiological reasons, of extreme interest and importance, for cultivating the motor centres of the brain between the ages of four and fourteen, and, consequently, against "cramming it with decimals and geography while the hands hang flaccid and the digits grow clumsy and stiff." All the same, Dr. Crichton-Browne entirely approves of the Education Act, and would not reduce the period assigned by it

Digitized by Google

to elementary schooling. He asks chiefly for some mitigation of the demand of inspectors in respect to compulsory and class subjects, in order that time may be found for manual training. He has not much faith in the workshops which have been superadded to some of the Board Schools, and which have utterly failed, partly because the scheme is too ambitious, but largely, no doubt, because the pupils have had no early training in those manual dexterities which the author so much desiderates. What he recommends is that drawing and modelling be taught from early infancy, and continued till the boy or girl leaves school. In the infant school these arts should occupy half the school-time, and in elementary schools much more time than is at present given to them.

These propositions, at first sight, appear rather startling; but hey are based not merely on the physiological facts which examination of brain functions have recently disclosed, but on the indisputable characteristics of the Anglo-Saxon race. The report of the Royal Commission on Technical Education proves to demonstration that there is no race to compare with ours for natural—that is to say for inherited—skill in all manner of handicraft. It is the fear lest this characteristic of the race may be lost to us if we occupy the best years of our children's lives in mental and non-manual exercises that has induced Dr. Crichton-Browne to plead for the latter with such earnestness and vigour. Not the least instructive portion of his paper is taken up with evidence that our real or supposed losses of trade are not due to any inferiority in our technical skill, but to other and quite different causes. Nevertheless, it may be feared that the apprehended inferiority will become a reality if we do not take steps to prevent it; that is to say, if we stop the natural course of heredity which has hitherto given the children of our handicraftsmen a natural aptitude for handicraft—an aptitude which was formerly, and ought to be still, cultivated while the brain and the hands are still young.

An interesting consequence of the extension of electric lighting under the amended Act will arise from the necessity for the appointment by the local authorities of Inspectors of Electric Lighting. The chief duties of this important functionary will consist in the testing of both main and service lines for insulation and conductivity and in the testing and certifying of meters. He is also empowered, "at all reasonable hours," to have access to and to test any instruments which the undertakers may be required by the Board of Trade to set up in the central station for the purpose of recording such observations as the Board may from time to time prescribe, "and if the same are not in order he may require the undertakers forthwith to have the same put in order." The undertakers are, moreover, compelled to provide all due facilities for the proper execution of such tests, and in default of compliance they will become liable to a penalty of five pounds, and a further penalty of one pound per day for every day after the first day during which such offence continues. The tests of mains for conductivity and insulation are not to take place more often than once in three months. What will happen if the tests prove unsatisfactory we have been as yet unable to discover. It is, however, to be hoped that the penalty for permitting defective insulation is of a thoroughly deterrent character. Either the undertakers or the consumers are at liberty to require the inspector to test the accuracy of any current or energy meter, and the party making the demand is to pay the Inspector certain fees, which fees the said Inspector is either to pocket or to hand over in relief of the local rates, as the local authority by whom he is appointed may see fit to determine. If, however, a consumer provide his own meter, and the undertaker require an inspection thereof, the said consumer is himself to pay the fee if the said meter be certified by the Inspector to be incorrect.

With duties so onerous and delicate as these it is satisfactory to note that the Act requires that the Electrical Inspector be a "competent and impartial person," and furthermore that the local authority shall provide him with suitable and proper appliances wherewith to carry out the tests. It is also provided that the local authority "shall pay to every electrical inspector such reasonable remuneration (if any) as may from time to time be determined by the said authority." The rate of emolument is therefore not to be unreasonably high; but, on the other hand, it may be nothing at all. The position will of course be one of considerable dignity and pride, since it demands familiarity with the art and mystery of a craft very little understanded of the people; but we doubt whether many competent and impartial persons will be found to do the work for the honour of the thing. Speaking seriously, the proper performance of the inspector's duties will be of no little importance to the smooth working of the Act, and we trust that due care will be taken for the appointment of properly qualified men. The position will evidently demand a good deal of common sense as well as a competent knowledge of electrical measuring instruments and methods of testing.

In this connection there also arises the important question of *Quis custodiet custodes ipsos?* The appointment by the Board of Trade of an Electrical Inspector-in-Chief cannot long be deferred. It is much to be hoped that this appointment will fall into the hands of some one qualified not merely by technical knowledge and ability, but also by actual experience of electrical engineering on a commercial scale.

The non-technical interviewer, when practising his calling upon a well-informed inventor, is in much the same predicament as the non-technical judge who is trying a technical case, only considerably more so; and, on the other hand, the person interviewed is beset with the same temptations as those to which the skilled witness has been known to succumb. A curious illustration of the severity of this temptation is to be found in a recent interview between the representative of an important London firm and the reporter of an enterprising newspaper in South Wales. This paper has employed the electric light in its own offices for a considerable time past, and a knowledge of this fact evidently proved of considerable value to the interviewed one in his endeavour to say nothing extravagant on the question of the comparative cost of gas and electricity. But it

Digitized by Google

is our sad duty to record that after struggling manfully with this temptation, the interviewed one fell at last lamentably and hopelessly (where many a better man, perhaps, has fallen before) when he came to speak of secondary batteries. "You may," he said, "safely lay down these batteries and be confident that they will require no attention or looking at, though in constant use for a period of two years and a-half" (!)

THE extension of the telephonic inter-urban communication continues to progress apace in the Midland and North-country districts. At the meeting of the National Telephone Company, on Saturday last, some very interesting particulars were furnished by Colonel JACKSON. Birmingham is at the present time the centre of activity, and four important lines radiating from this centre are now in course of construction, and will all be completed within a few months. Three of these lines will severally connect Birmingham with the Potteries, with the Lancashire and Cheshire, and with the Yorkshire system; while the fourth is the line to London, of which we have already given particulars. When these extensions are complete the Metropolis will be within speaking distance, *viâ* Birmingham, of practically the whole of the important commercial centres of the Midland, Northern, and North-Western districts, and we shall be curious to learn what sort of service the United Telephone Company will then be able to give us.

IN France the question of long-distance telephony wears a somewhat different aspect to what it does in this country, owing to the fact that while the local exchanges are chiefly in the hands of private companies, the trunk lines have been built by the Government. At present the Paris-Marseilles line is only available from the head offices, and the high tariff of three francs for three minutes' (or five, the accounts differing) conversation is charged. The daily papers are speaking of this line as the longest hitherto built for telephonic purposes. As a matter of fact, the distance from Paris to Marseilles is only about three-quarters of that from New York to Chicago, which cities have been for some time in telephonic communication.

IT is to be feared that in their anxiety to disparage the electric light some of our gas lighting contemporaries are willing to lay hold of almost any weapon which can be made to serve their turn. For instance, one of the journals recently published a paragraph under the heading of "The Dangers of Electric Light Installations in Thunderstorms." This paragraph read as follows:—"The residence of Sir Albert Sassoon, in Eastern-terrace, Hove, narrowly escaped destruction by fire on the night of Sunday, the 22nd inst. During the heavy thunderstorm which occurred that night one of the maids, who had been roused by the storm, was startled by a smell of fire coming from the entrance hall, which is lighted by incandescent electric lamps. The girl called the butler, who found that flames were flickering near one of the lamps. He poured some water upon the spot, and in this way the outbreak was checked. One of the lamps was broken, and the woodwork near it scorched. It is supposed that the wire was struck by lightning, which was thus conducted into the house." But on making inquiries as to the accuracy of this story we received the following letter from the Brighton Electric Light Company:—"In reply to your favour of 1st inst. with reference to enclosed cutting from the *Gas Journal*, we beg to advise you that the electric light installation at Sir Albert Sassoon's was totally disconnected from our outside mains during the whole of last month. The accident that occurred was attributed by the fire insurance inspector to the lightning striking a very elaborate weather vane on the roof, which conducted it into the house in close proximity to one of our brackets, on which there were electric wires and lamps."

THE obvious lesson to be learnt from this incident is that it is unsafe to erect weather vanes which are not at the same time treated as lightning conductors and provided with a good earth contact. As to the comparative degree of danger produced by gas and by electric fittings during a thunderstorm, that obviously depends in part on the special circumstances of the case. Other things being equal, gas is certainly the most dangerous, from its liability to be set alight. Three distinct instances in which this has actually happened have come to our notice within the last few days. But it must be admitted that overhead wires introduce a certain element of danger of their own, which may, nevertheless, be guarded against by the use of an efficient lightning protector. We should be glad to see a clause to this effect incorporated in the next edition of the Phœnix Fire Office Rules.

IN the "tetantograph" with which the *Daily News* has threatened a long-suffering generation our readers will probably have recognised the somewhat less cacophonously named "telautograph" of Prof. ELISHA GRAY. Prof. GRAY has evidently taken a leaf out of EDISON'S book (which, after all, is perhaps only tit for tat), and for a long while past he has been careful to remind the public at intervals that he is engaged in inventing or perfecting a writing telegraph. The information now vouchsafed lays stress upon the fact that a "pulsatory" current is used instead of a "variable" current. This may or may not be a valuable improvement, but it does not at present enable us to see in what way the telautograph is going to surpass ROBERTSON'S modification of COWPER'S instrument, either in simplicity or in reliability. Neither have we as yet discovered the exact nature of the service which the Writing Telegraph, however good in itself, is destined to fulfil. In the regular telegraphic service it is too slow for all but the least important lines, where cheap and simple apparatus is the chief requirement; while for public use it can scarcely expect to displace the telephone.

WE are officially informed that Mr. HUGH WATT, M.P., has resigned his position of director and manager of the Maxim-Weston Electric Company, and that the Board has accepted the resignation. The engagement of Mr. J. WRIGHT (the secretary) has also been terminated, and the company's offices have been removed to No. 2, Metal Exchange-buildings, Gracechurch-street. The Liberal Association of the Camlachie Division of Glasgow has likewise asked Mr. WATT to resign his seat for that constituency. Commenting on these announcements the *Financial News* says: "This is so clean a sweep as to suggest

Digitized by Google

the Brush rather than the Maxim-Weston; in fact, Mr. WATT had better begin to resign himself—to the inevitable."

The Globe makes merry over Mr. VERNON HARCOURT'S holophotometer thusly:—"We are compelled to admit that we do not understand much of the description of the 'Holophotometer.' But, as far as we can make out, it has something to do with Mr. GLADSTONE. In the first place, it is invented by VERNON HARCOURT (though not 'Sir,' but 'Mr.'); secondly, its object is to 'measure the light emitted in every direction by a luminous source,' and we all know that Mr. GLADSTONE is considered by his party to be the source of all light; and, finally, its technical description is 'an axis working friction-tight in a *collar*.' If this is not Mr. GLADSTONE, what is it?"

Train Lighting.—We learn that the Midland Railway Company are now going to try the electric light for some of their local trains.

The Transvaal.—The Transvaal line of telegraphs has, we learn, been extended to Pietersburg, which is about twelve miles from Eersteling.

Milan.—The Milan Omnibus Company has appointed a committee to consider the desirability of adopting electric traction on the line from Milan to Conza.

The Hansthohn Lighthouse.—We learn that Messrs. A. de Meritens and Co., of Paris, are about to furnish the electric plant for the lighthouse of Hansthohn, Denmark.

The Direct United States Cable Company.—We are informed that this company's main cable between Ireland and Halifax (Nova Scotia) is now in efficient working order.

The Cox-Walker-Swinton Magneto Bell.—In reference to our description of these appliances in our last issue, we are requested to add that the Equitable Telephone Association has been appointed sole agents for their sale.

The Mechanical Engineers at Bessbrook. — The members of the Institution of Mechanical Engineers, which is now holding its annual summer meeting at Belfast, paid a visit on Thursday, 2nd August, to Bessbrook, and inspected the electrical railway.

Annual Outing of Messrs. Immisch and Co.'s Workmen.—On Saturday last the sixth annual summer excursion of the *employés* of Messrs. Immisch and Co. took place at Rickmansworth. The party, numbering about eighty-five, drove down by road, and spent a very enjoyable day.

The American Electric Light and Telephone Associations.—The eighth meeting of the National Electric Light Association will be held in New York on August 29th, 30th, and 31st, and the tenth annual convention of the National Telephone Association will also be held in the same city on September 4th and 5th.

Theatre Lighting.—We learn that the contract for lighting the Shakespeare Theatre at Liverpool has been secured by Messrs. Hills and Thomson, of 62, Dale-street, Liverpool. It is intended to use a gas engine as the source of motive power, and accumulators will be introduced. A number of Sunbeam incandescents of about 150 candle-power will be used.

The Atlantic Cable Rates.—The Anglo-American, the Direct United States, and the Commercial Companies have given public notification that on and after the 1st prox. the rates for the transmission of ordinary telegrams from the United Kingdom to New York by their system will be 1s. per word, and for press messages 5d. per word.

Innsbruck.—Messrs. Ganz and Co. have just established a central lighting station on the transformer system at Innsbruck. The station is some five miles outside the town, and the motive power is obtained from a waterfall. The primary current is conveyed to the town by an underground cable. At present 3,000 lamps are in use, but before long the number will reach 6,000.

New Incandescent Lamp.—Messrs. Woodhouse and Rawson are bringing out a new form of lamp adapted for ship work, where the vibration, especially on board men-of-war, considerably shortens the length of life of the lamp. In this new lamp the filament, although requiring the same E M.F. and giving the same candle-power, is of higher specific resistance. We shall shortly be able to give some further information on this important subject.

Rapid Cabling to Australia.—The Governor's messages to the Queen and Prince of Wales announcing the opening of the Melbourne Exhibition, consisting of 117 and 86 words respectively, were transmitted between Melbourne, *viâ* the Eastern Company's lines, and London in thirty-eight and forty-nine minutes respectively. Her Majesty's reply of congratulation, consisting of thirteen words, reached Melbourne in sixteen minutes after its receipt at the London station.

A New Submarine Cable Company.—The *Bulletin de l'Electricité* announces the formation of a French submarine cable company, with a capital of 5½ million francs, to purchase work, and lay down a network of cables between Venezuela, Curaçao, Hayti, Cuba, and the United States. The company is called the Société Français des Télégraphes Sous-Mairnes, and is intended to acquire the rights granted by the various Governments to MM. Jules Lair and Paul Wallerstcia.

Temesvar.—The Anglo-American Brush Electric Light Corporation, who have for some years carried out the public lighting of the streets at Temesvar on the Brush series-multiple system, have decided to undertake the lighting of private houses also, and to adopt for that purpose the Zipernowsky-Déri-Bláthy system of transformers. The Brush Company has already ordered the necessary material for this new installation, which is to be furnished by Messrs. Ganz and Co., of Budapest.

Telegraphic Communication with Lighthouses.—In the House of Commons on the 5th inst., Sir M. Hicks-Beach moved the second reading of Lloyd's (Signal Stations) Bill, and explained that its object was to improve the telegraphic communication at present existing between the mainland and lighthouses. The association known as Lloyd's were willing to undertake the work to a certain extent, and the Bill empowered them to take land for the purpose. The Bill was then read a second time and referred to a select committee.

The Phonograph.—We are pleased to learn from Colonel Gouraud that Mr. Edison has cabled him that, in deference to numerous requests, he has despatched several phonographs to be placed at the disposal of the scientific and learned societies of Great Britain, in such a manner as Colonel Gouraud may determine, and, so far as possible, in the order of priority of dates of the applications received. These instruments will contain several new devices for rendering audible to small audiences the sounds emitted. Colonel Gouraud has been invited to read a Paper on the subject at the forthcoming meeting of the British Association.

The Metropolitan Electric Supply Company.—We learn that owing to the lateness of the present Session the Metropolitan Electric Supply Company have dropped the Bill which sought the confirmation of a provisional order recently granted by the Board of Trade for lighting with the electric light the

Digitized by Google

parishes of St. James's, Westminster, St. Martin's-in-the-Fields, Waterloo Bridge, and a portion of the Victoria Embankment. This Bill, which was the only Electric Lighting Bill introduced in the present Session, had passed the examiners, but opposition had been threatened by the parish of St. James's and a competing electric lighting company.

"How it Strikes a Contemporary."—"The electric lighting engineers," says the *Journal of Gas Lighting, Water Supply, and Sanitary Improvement*, "appear to be a very jolly and social set of fellows, at any rate; for although they are necessarily living in the sharpest competition with each other, and are always treading on one another's toes in the matter of patents, they are ever ready to meet formally or informally, at a dinner or in a lecture room, and combine for pleasure or business purposes with a cheerful alacrity that might be emulated with advantage in other callings. The reason for this probably is that they are all educated gentlemen. It requires an underbred man to be spiteful and jealous in business relations."

An Improved Magneto Call Bell.—We have recently examined an improved magneto call bell, for telephonic and general purposes, introduced by the Telegraph Manufacturing Company, of Helsby. Externally—but for the smaller size and better finish—the apparatus is similar to the well-known American pattern; a closer examination, however, shows several important mechanical improvements, the driving wheel, for instance, instead of having the boss of the wheel only as a bearing, is mounted on a tubular shaft, through which the driving axle passes. An inclined slot arrangement causes this axle to move forward when rotated, pressing a contact spring, which brings the armature coils in circuit in the usual way; the continuity of the circuit does not, however, depend on the axle bearings, as is the case in the old pattern. The bearings are of hard brass, ensuring the least possible wear, and the design is such that the whole of the working parts can easily be removed for inspection or repair. The entire apparatus seems to be of first-class manufacture.

Exports of Telegraphic Wires, &c.—The satisfactory features of the Board of Trade returns for July, issued on Wednesday last, are not reflected in the exports of telegraphic apparatus. The exports of metals, ironwork and machinery were exceptionally favourable both for July and for the previous six months, but the exports of telegraphic wire and apparatus were exceptionally small. The following is a comparative statement to date:—

Exports of Telegraphic Wires and Apparatus connected therewith.

	1886.	1887.	1888.
1st Jan. to March 31st	...£124,074	...£131,879	... £88,077
1st April to June 30th	... 354,331	... 56,933	... 156,136
Six months	478,405	188,812	244,213
July	219,463	195,950	21,571
Seven months	...£697,868	...£384,762	...£265,784

The July exports this year have been almost the smallest of any month so far, while in 1887 and 1886 the July exports were up to date by far the largest.

Electrically-formed Copper Pipes.—Lloyd's Committee have recently had their attention directed to the increasing number of accidents arising from the bursting of copper steam pipes, chiefly in marine engines, in consequence of the high steam pressure which it is now customary to employ. In our issue of March 2, page 436, will be found a description of the interesting process introduced by Mr. Elmore, of Cockermouth, for forming seamless pipes by means of electro-deposition. Mr. W. Parker, the chief engineer surveyor to Lloyd's, has recently investigated this process, and has furnished a report to the committee. From this it appears that at ordinary temperatures the tenacity of the deposited metal is equal to 23¾ tons per square inch, as against 20¼ tons and 14 tons per square inch for solid drawn and rolled sheet copper respectively. At the temperature of high pressure steam the tensile strength of ordinary sheet copper does not exceed 10 tons per square inch, while the deposited metal stands equal to that of solid-drawn copper at 15 tons per square inch. The ductility of the deposited copper is, however, far higher than that of the solid-drawn, while its uniformity of structure is remarkable. Under these circumstances the introduction of these pipes on a large scale would seem to be only a question of cost.

An Invisible Lightning Flash.—The Paris correspondent of the *Daily Telegraph* writes as follows:—"A curious case of death by lightning has just occurred at Puy-de-Fourche, in the Department of the Dordogne. A farmer named Verneuil was at work in the fields with his family and some neighbours, when a thunderstorm came on. The whole party had sought a refuge from the rain under a large tree, when some one remarked that this was rather an imprudent step. They accordingly determined on moving off to a small wood at a little distance, and quitting their shelter they ran towards it as fast as their legs could carry them. When, however, they had got about half-way one of Verneuil's daughters, a girl of fourteen, stopped suddenly and slowly returned to the tree which they had left. Some of her companions followed to remonstrate with her on her rashness, but ere they could reach her they saw her throw her arms with a smile round the trunk. A moment afterwards the poor child fell backwards on the ground, with her arms outstretched, quite dead. Very strangely they had not perceived any flash of lightning or noticed any clap of thunder at that time. The girl, however, had been killed by the electric current, as the careful examination made afterwards proved conclusively."

Alleged Restoration of Sight from a Flash of Lightning.—A paragraph with the above heading appeared in a Wolverhampton paper, and has been copied into several London journals; it affords a good example of the very flimsy evidence that suffices to render the marvellous credible to the general public. The case has been investigated on behalf of the *British Medical Journal*, which says that so far as can be ascertained the facts are briefly as follows:—"The patient was injured by an explosion in a mine; one eye was totally destroyed, and he became unable to see with the other. He was in the hospital for seven weeks for 'fits,' and on leaving was led about owing to his defective sight. One evening, after a flash of lightning, he noticed that he 'could see indistinctly objects near to him,' and a few days later he could see to walk about without a guide. On inquiry we learn that for some time after the patient could only partially open the eye, that the cornea was opaque, and had been gradually clearing for many months past. In the absence of any authoritative statement as to the condition of the vision before and after the lightning flash, there seems no reason for assuming that the case was anything but an ordinary one in which the cornea was slowly clearing. Nothing is more common than for a gradual improvement to be suddenly noticed when it has reached a certain stage."

Electrical Conductivity of Metals and other Physical Constants.—The fact that the electrical conductivity of the various metals is in the same relative order as their heat conductivities is a commonplace of the text books, but Prof. Kundt has recently shown (*Phil. Mag.*, July, 1888) that the analogy also extends to the velocity of light in metals. This

Digitized by Google

velocity is easily calculated when we know the index of refraction. Hitherto the indices of refraction have only been known for certain metals, and by indirect methods of observation, but Prof. Kundt has succeeded by means of electrolytic deposition in preparing metallic prisms of very small angle and sufficiently transparent to admit of the direct measurement of the refractive indices. The relative velocities of red light in seven metals, calculated from these observations, are as follows —

Silver	100	Iron	14·9
Gold	71	Nickel	12·4
Copper (impure)..	60	Bismuth (crystallised).	10·3
Platinum.....	15·3		

The order will be seen to be the same as that of the relative electrical conductivities. The number 60 for copper appears to be too small, but Prof. Kundt thinks that this is probably due to the existence of traces of cuprous oxide in the prism. He is now engaged in investigating the influence of a magnetic field upon the velocity in question.

The Electric Resistance of Copper at Low Temperatures.— A contribution to this subject has just been made by M. Wroblewski, who undertook to test the truth of Clausius' remark in 1856 that the electric resistance of chemically pure metals should be proportional to their absolute temperature. That is to say, if the temperature of a metal could be reduced to the absolute zero, would its conductivity increase to infinity? M. Wroblewski took advantage of one of the new methods of producing intense cold by the evaporation of liquefied gases. Copper wire of about 4·100 millimetres in diameter, covered with a double layer of silk, was taken, the conductivity being guaranteed as 98 per cent. of that of pure copper. With this wire M. Wroblewski wound a number of small bobbins having a resistance at ordinary temperatures of between 3 and 20 Siemens units As the bobbin had to be plunged in liquefied gas, M. Wroblewski began his investigation by studying the electric properties of liquid oxygen and nitrogen. He found that these substances ought to be ranked among the most perfect insulators. The resistances of the bobbins were then measured by the Wheatstone-Kirchhoff method at the temperature of boiling water; at the ordinary temperature; the temperature of melting ice; the temperature of boiling ethylene at atmospheric pressure (−103° C.); the critical temperature of nitrogen (−146° C.); the temperature of boiling nitrogen under atmospheric pressure (−193° C.); and a temperature nearly that of the solidification of nitrogen (−200° C. to −202° C.). The results are embodied in the following table, where t is the temperature, r the resistance in Siemens units, and a the coefficient of variation of resistance between two consecutive temperatures :—

Bobbin I.			Bobbin II.		
t.	r.	a.	t.	r.	a.
deg. C.			deg. C.		
+100	5·174	—	+23·75	19·251	—
+ 21·4	3·934	0·004365	+23·75	17·559	0·004075
—	—	—	−103	9·848	0·004263
−103	2·073	0·00414	−146	6·749	0·004104
−146	1·360	0·004588	−193	2·731	0 004869
−193	0·580	0·004592	−201	1·651	0·007688
−200	0·414	0·006562	—	—	—

These numbers seem to show that the resistance actually decreases much more quickly than the absolute temperature, and approaches *nil* at a temperature not very far from that obtained by evaporating liquid nitrogen in a vacuum. In view of this remarkable result it is to be hoped that the question will receive further investigation.

Injury by Lightning.—In the *British Medical Journal* Messrs. A. H. Cook and William Boulting give a detailed account of a case of serious injury by lightning which occurred at Hampstead during one of the recent storms, from which we extract the following:—"About 1 p.m. on June 14th, 1888, W. F., aged sixty-two, and D. H., aged forty-two, sawyers, were working in a wood at the Spaniards Farm, near Hampstead. There was no rain nor any sign of a thunderstorm at the time. The men were eating their dinner under an oak tree, their saws, six and a-half feet long, leaning against the fence, about two feet from the trunk. One of them, F., was standing leaning against the trunk, while the other, H., was seated on a block of wood about three feet from it, with his open knife resting upon his knee. Suddenly H. 'saw the clouds open and a sheet of fire falling.' He heard a deafening thunderclap, and felt stunned for some minutes, but had no sensation of pain. Then he discovered that his trousers were on fire, smoking but not blazing, and that his knife had been knocked out of his hand, and his steel buckles torn from his legs. He saw F. lying senseless on the ground and quite still, as though he were dead. He had lost all feeling in his legs, and he tumbled down when he tried to walk. His boots were 'in ribbons,' and fell off when he moved. He managed first to quench the fire in his trousers, and then to crawl to the road near by shouting for assistance. He was somewhat deaf, but could hear himself shout, and 'felt as though he had been blown from a cannon.' F. says that he remembers nothing of the accident, and neither felt nor saw anything. Insensibility must have been instantaneous. H. managed to attract the attention of some men passing in a cart, and both men were conveyed to the infirmary, F. still quite unconscious, and his clothes torn off him to such an extent that for decency's sake he had to be covered with one or two sacks on admission. In the absence of Mr. Cook, the medical officer, they were seen by Mr. William Boulting, a neighbouring practitioner, who saw the men an hour and a-half after the accident, and found them in a state of intense collapse. The features were ghastly blue, with a dull yellowish-white showing through the leaden colour. F. was almost pulseless, but became slightly conscious on being roused. H. was groaning, and complained of a burning pain as from a red-hot iron, which was 'travelling up his legs.' Their clothes were cut from them, and F. was found to have burns on the right side from his shoulder to his feet, bearing the appearance of abrasions. The whole of this side (presumably the side on which he was leaning against the tree) had exactly the appearance of an exaggerated example of *post-mortem* staining. H. had his legs burnt in places from the point where he had been resting his knife downwards. The legs were cut, probably by the steel buckles he had worn. His pulse was intermittent at the time, and for several days after the accident. Since the accident he had been so deaf that he could not hear a watch laid against the ear on either side or when held between the teeth. On July 9th he could hear a watch at a distance of four inches from the left ear, and was much less deaf. The oak tree was found to have been struck about fourteen feet above the ground, leaving a track all the way down. The exact position of the men and of the long metal saws which doubtless attracted the discharge to the tree under which they were was as follows:—The fence passed close to the tree, the saws were leaning against it at a distance of about two feet from the trunk. F. was leaning with his back against the trunk about a yard, and H. on the opposite side of the fence was sitting about two yards distant from the saws. The case illustrates the danger of the proximity of steel instruments during times of electric disturbance. Nor should it be forgotten that without lightning dangerous return discharges from the earth to the atmosphere may take place at a considerable distance from an atmospheric storm."

THE ANGLO-AMERICAN BRUSH CORPORATION'S ELECTRICAL ENGINEERING WORKS.

We recently paid a visit to the factory of the Anglo-American Brush Electric Light Corporation at Lambeth, with a view to the following descriptive account, which we feel sure will be of much interest to our readers. It is scarcely necessary to say that there are very few electrical engineering enterprises in this country which can be compared either in importance or magnitude with that carried on by the Anglo-American Brush Corporation. From a technical and an engineering point of view the operations of this company have been characterised by a long and unbroken series of successes, which reflects the highest possible credit upon the technical staff, whose inventive genius and mechanical skill deserves, as it has indeed received, a wide recognition. From a commercial point of view, the history of the company has been of a chequered and somewhat remarkable character, but the present board of directors, with their able staff, have made great and by no means unsuccessful efforts to establish the company on a sound and permanent basis. Of the extent to which the foundation—and something a good deal more than the foundation—of a career of prosperity has now been laid our readers will be better able to judge after reading this description.

The works in Belvedere-road, Lambeth, cover an area of about 28,000 square feet, and consist of three separate main buildings, each of three floors, besides an iron building containing drawing and works manager's offices. The first of these is devoted to the offices of the board and the staff. The second contains the dynamo and arc lamp factories; to this there is also attached a smithy, an erecting shop, and a building of one story where the greater part of the testing work is carried on. In the third building chiefly women and girls are engaged in the manufacture of incandescence lamps. It would be a mistake to suppose that all the secrets of lamp making have been disclosed during the late proceedings in the Court of Chancery, and for that reason our lips are sealed with regard to the contents of this building. We return, therefore, to the second department, where there is enough of interest to be seen in the various processes of manufacture of the Brush and Victoria dynamos, the Mordey alternator and transformers, the Brush and Brush-Sellon arc lamps, together with motors, projectors, switches and minor fittings innumerable. It is not, however, our present purpose to enter upon any description of these apparatus, which at various times have all been described and illustrated in *The Electrician*.* We have now to do chiefly with the machinery and with the organisation by which they are produced.

The heavy tools are placed on the ground floor of one of the three-story buildings already mentioned. Here there is every appliance for dealing with the large masses of iron with which modern electrical machinery is built up, including a powerful traveller, which passes overhead along the whole shop. At one end is a horizontal Galloway engine of about 150 horse-power, which supplies motive power to the whole of this building. Steam is generated in a couple of Galloway boilers, placed in the adjoining boiler house. The principal tools in this shop are large planing machines, shaping machines, some very fine radial drills, and a substantial row of heavy lathes, together with numerous milling machines and other tools; lastly, though not least interesting, we find here some special tools adopted in the factory for building up the iron cores of the modern Brush armature. As our readers are aware, the Pacinotti projections of this armature consist of a very large number of various-sized stampings of sheet iron. By means of special jigs, the apparently difficult operation of building up this structure with the necessary uniformity and rigidity is easily and rapidly accomplished. This shop is lighted all day by electricity. For this purpose a large Brush dynamo, driven by the engine already mentioned, supplies 55 arc lamps in this and other parts of the building. Every lamp has its own switch, and as the current from the same machine is employed in the adjacent lamp factory, and also for some of the testing work, the load on the dynamo is very variable. But by means of the Brush automatic regulator—which, it will be remembered, consists of a variable carbon shunt upon the field—the lamps burn with remarkable steadiness, and the current is maintained almost perfectly constant at 10 amperes. At the time of our visit many tons of wrought and cast iron were being planed and turned up for the construction of dynamos.. Every portion of these dynamos, of whatever size, from 1,500 up to 75,000 watts (which happens to be the largest size at present in progress), is made to template, so that all the parts are interchangeable. The largest possible number of machines of the same type is put through at the same time, so as to economise the work of the factory to the utmost. Unfortunately for incandescent machines, so many different voltages, outputs, and speeds are demanded that it is impossible to carry out this principle to the fullest extent. It is much to be hoped that dynamo makers will shortly see their way to adopt some united course of action in this respect.

Adjoining this shop, and on the same floor, is the erecting room, where the machines are erected and finished ready to be sent out after being thoroughly tested. Here also is a travelling crane driven by high-speed rope gear, by means of which parts of dynamos or the entire machines are rapidly placed in any required position. Amongst a large number of machines here approaching completion we noticed a 40-unit Mordey Alternator of the type recently introduced by the Brush Corporation. This machine has abundantly fulfilled the expectations formed of it, and since its description in this journal the only improvement it has been found desirable to make consists in the substitution of porcelain for wood in the flat sector-shaped cores on which the armature coils are wound. Another interesting machine which attracted our attention was a low-tension Brush dynamo, designed for train lighting on the London, Brighton and South Coast Railway, and also in use on several other lines. These machines are driven by a belt from the axle of the guard's van, and are used in connection with an accumulator of about 25 cells. The machine gives a constant E.M.F. over a wide range of speed, so that no regulating device of any kind is needed. The brushes are brought to bear on the commutator, by an automatic arrangement, as soon as the train is running at a speed of 10 miles per hour. Two sets of brushes are fitted, which come into use alternately as the van runs backwards or forwards. On the London, Brighton and South Coast Railway and the Great Northern Railway these machines have been in use for some years. The dynamo and accumulators are placed in a locked compartment of the guard's van, and are found to be quite capable of taking care of themselves upon the journey. Here also we noticed a 15-unit Victoria machine, ordered by the War Office for installation in a certain fortification, for which purpose over 30 similar machines have already been supplied.

Ascending to the first floor, which is the light turnery department, we found some seventy or eighty men engaged, chiefly on lathe work, turning out the transformers, brass fittings, arc lamps, projectors, switches, lamp-holders, &c., &c. The projectors made by the Brush Corporation are largely employed for military and naval purposes, and for navigating the Suez Canal, and doubtless their use will extend in the mercantile marine for navigating other narrow channels at night. An ingenious but simple dioptric electric side light for steamers, of quite recent design, was here undergoing completion. An incandescent lamp is placed in the focus of the lantern, and by means of an electro-magnet whose armature retains a spring-catch, if the lamp burns out, not only is a second lamp immediately lit up, but it at once replaces the first in the focus of the lens. This practically does away with the objection which has hitherto been felt against the electric side lights. Considering the scale upon which the manufacture of the Brush arc lamp is now carried on we need hardly say that every part of the lamp is made to template, but our readers will perhaps

* *See* the following numbers of *The Electrician*:—The Brush dynamo, February 3rd, 1883, p. 271; March 3rd, 1883, p. 379; August 9th, 1884, p. 304, Vol. XV. Digitized by Google

be surprised to learn that so great is the accuracy with which some portions of the apparatus are turned out that an inaccuracy of $\frac{1}{2000}$ inch determines their rejection. In order to secure this extreme nicety the greater part of the work is carried out by specially designed tools, most of which are automatic in their action. We cannot, of course, enter upon any description of these appliances, some of which are extremely beautiful and ingenious, and are the results of a great deal of thought and mechanical skill.

For cutting spur and bevel gearing for the projectors and arc lamps, an automatic tool is used, which was also designed in the works. The iron plates for the Mordey transformer are stamped out on this floor by a power press, attended by a boy, which works at the rate of twenty-five strokes per minute. Another boy then slips the outer and inner stampings alternately through and over the long coil, and the transformer is thus quickly and cheaply put together. A special and somewhat dirty compartment on this floor is occupied by the "buffing" machinery, where the highest polish is given to the work requiring it.

On the third floor are the pattern and the winding shops. The iron cores of Brush and Victoria dynamos which were seen in course of construction on the ground floor here receive their copper coils. Some surprise is often expressed that the coils of high tension dynamos so very seldom give rise to insulation troubles. But while watching the operation of winding a large Brush armature designed for an E.M.F. of 3,000 volts, we perceive that the greatest possible care is taken with every inch of the conductor, and the work is only entrusted to those men who by long experience and skill are thoroughly qualified for the task. In the Victoria armatures, all the larger sizes are wound with copper strip, and the details of the old style of Gramme winding are somewhat departed from. Instead of winding each coil separately and connecting its own end to the commutator—which involves a considerable twist in the wires—the whole core is wound continuously with one length, and the commutator bars are connected by separate wires which are securely fastened to the armature conductors.

Returning to the ground floor, and passing through the erecting shop, we arrive at the testing room. In this room there are racks provided with dark glasses for testing and adjusting arc lamps, and as many as eighty lamps are sometimes tested at the same time upon a single circuit. Motive power is furnished in this room by a couple of 70 horse power engines and boilers. These engines drive on to a counter-shaft, which is fitted with a claw clutch, so that one or both engines can be used in the same work, or each engine may be used separately on its own half of the counter-shaft, so that various operations demanding different speeds may be carried out at the same time. When large dynamos have to be tested whose output exceeds the joint power of the engines, a portion of the current from the machines is carried to an electro-motor whose pulley is belted back on to the counter-shaft. This modification of Dr. Hopkinson's method of testing is often useful in enabling heavy work to be economically dealt with even when the full power of the engine is not exceeded by that of the dynamos. For power tests for motors, or dynamos, there is provided a transmission dynamometer, designed in the drawing office of the works. The apparatus may also be used as an absorption dynamometer, by attaching a friction brake to one of the pulleys.

In the adjoining courtyard we come to another small engine house, which contains a "Brush" vertical engine, driving a 10-unit Victoria dynamo by means of the Raworth friction gearing. This forms an excellent combination for use where it is desired to supply a small installation with the minimum amount of trouble and attention to the engine, the advantage being that the friction pulley enables the dynamo to be driven at the required speed by means of a comparatively slow running engine of the simplest possible type, one which can be put into the hands of the most ordinary mechanic or engine driver with the certainty that he will find no point in its management beyond his skill. This machine is compounded (as most of the Victoria machines are) exactly to suit the special conditions under which it is working—that is to say, it maintains a constant potential difference at the end of its leads through any variation of load, and also corrects for the 5 per cent. irregularity of speed which is permitted by the governor of the engine. We may add that for ship lighting a very large number of these sets has been supplied, it being found that their simplicity and reliability admirably adapt them for use on long voyages. We were informed that one, supplied to an Orient liner, had just returned into port after a voyage to Australia and back, the total stoppages amounting to only 23 hours, and this due to the ship being in port and not requiring any lights, and not to any mechanical or electrical necessity. It is in this department of ship-lighting that some consolation has been found for the slow development of land work, but now that Lord Thurlow's Bill has become law, and the electrical atmosphere cleared in other respects, we fully anticipate that the electric light will become at least as common on shore as afloat.

At this point we may also refer to the fact that the Brush Corporation has for some time been devoting special attention to the subject of the electrical transmission of energy, and particularly to electric traction. An arrangement has just been concluded by which they will have an opportunity of showing what can be done in this direction upon a large scale. We are unable to go into details at the present moment, but we may say that the scheme contemplates the use of electric traction upon a tramway some 10 miles in length, traversing a very hilly district, with grades and curves of the most severe character. An overhead conductor will be employed, and each motor will be constructed to develop more than 20 horse-power. We have every confidence that the scheme will be brought to a highly successful issue.

As an illustration of the extent to which the machinery and appliances which we have now briefly described is capable of dealing with a very large amount of work in a remarkably short time, we may quote an instance which has quite recently occurred. On the 23rd February an order was received from the Australasian Electric Company for 1,000 Brush arc lamps, 40 Brush dynamos, and 7 Victoria dynamos each of 3,000 20 candle-power lamps capacity, a condition being made that a guarantee should be given that the whole of the plant would be shipped within two months, it being required for the lighting of the Melbourne Exhibition. It so happened that very few Brush lamps were in stock at the moment, owing to demands for the exhibitions at Glasgow, Brussels and elsewhere, and of the Brush machines required only six or seven were then in stock. The order was, however, immediately accepted, and duly carried out within the specified time, and the plant is now at work lighting the Melbourne Centennial Exhibition. It will be evident to all that to obtain such results as these demand not merely adequate mechanical appliances, but also a highly skilled and intelligently organised staff, accompanied by the most careful supervision of detail. It is to the perfection of these minutiæ, and the development of the commercial side of its organisation, that this company has devoted itself during the comparative lull of the past few years.

It would, however, be of little avail for a firm to keep in touch with scientific progress if its organisation were such as to render the economical execution of contracts impracticable, and this is just what the officers of the Brush Corporation have so fully recognised. What may be called the economics of electric engineering find full application in the establishment of the Brush Corporation. This is exemplified by the fact that the volume of the Corporation's transactions is now nearly three times greater than it was five years ago, while the aggregate expenses of management have been reduced by over 40 per cent. This absolute reduction in the expenses of the establishment is the more surprising and creditable when it is considered what a large amount of work has been done which has not been remunerative in the past, and which has been incurred solely with the object of facilitating future operations, and making them more profitable. The records in the possession of the Brush Corporation show that the company has, during the past few years, laid open much new ground in various important branches of the electrical industry, and it naturally looks forward to reaping a

Digitized by Google

good harvest now that the conditions of the business have improved, while the careful analysis of cost of manufacture of a large variety of articles will enable the company to enter into close competition for orders without any uncertainty as to the result. The processes of manufacture are carried out in a systematic and economical manner, and there is much in the methods adopted for registering material and labour which is both instructive and interesting.

What strikes one more especially is the general thrift and absence of extravagance, and this is attributable in a large measure to the *esprit de corps* existing among all the *employés* of the Corporation. We have before us a striking evidence of this in the form of a neat set of rules for the Sick Benefit Club for the workmen, which has been spontaneously formed by the officers acting in concert with the men. We understand that there are close upon 200 regular subscribers to this club, and a reserve fund which has been created entirely by voluntary contributions by the staff and directors amounts to a very respectable figure, and affords a guarantee that in no case of sudden demand upon the funds of the club will there be serious risk of claims not being satisfied.

Another interesting feature is the adoption of the principle of participation in profits, which was sanctioned by the shareholders some little time back, upon the recommendation of the directors. This is not merely a scheme by which a few favoured officers receive commission corresponding to the business done, but is an instance of the true principles of co-operation being put into practice. Every officer who qualifies himself under certain general rules is eligible to be nominated as a participant. The arrangement is that a sum equal to 10 per cent. of the dividends is set aside as a fund to be divided in proportion to salary among the officers from time to time nominated by the Board. In this way the interests of the staff are made identical with those of the proprietors, and the experience of the past affords every reason for satisfaction with the operation of the plan.

The Brush Corporation, it will be seen, has shown much commercial enterprise and initiative, not only in the direction above indicated, in the admission of pupils and apprentices into the factory, or other internal affairs, but also in their efforts to develop the electrical industry in this country.

It is well known that the first practical steps taken with a view towards amending the Electric Lighting Act were initiated by the Brush Corporation, and that the Bill which has just received the Royal assent was successfully piloted through Parliament by the chairman of the Corporation.

Another reform which has received less attention, but which will be of much pecuniary advantage to electrical firms generally, namely, the re-classification of railway freights, was also largely brought about by the efforts of this company.

The introduction of the purchase hire system into this business has also done much to promote the extensive adoption of electric lighting. Firms who have been deterred from expending capital in introducing the new illuminant were enabled to do so by the facilities thus afforded them, and in this way the electric light has been more extensively advertised, and increased demands for it have arisen. We can only express surprise that other firms have been so slow to follow the example thus set them.

It would be impossible for us to dwell upon these and other matters at greater length, but we felt that a sketch of the company's work and resources for undertaking large contracts would not be complete without some notice of the important commercial features of its organisation which have so largely contributed to placing the Corporation in the position it now occupies.

Auckland, N.Z.—The Thomson-Houston Electric Company of Boston appear to be anxious to secure a footing in New Zealand. They are now endeavouring to promote a local company in Auckland, with a capital of £12,000, under the title of the Grey-Brumner Electric Company, to light the wharves and streets of that city.

ON THE THEORY OF LIGHTNING-CONDUCTORS.*

BY PROF. OLIVER J. LODGE, D.SC., LL.D., F.R.S.

That a condenser discharge is oscillatory has been known ever since 1858, when Sir William Thomson's great Paper "On Transient Currents" appeared. Quite recently it has been recognised, first quite explicitly perhaps, by Mr. Heaviside, in *The Electrician* for January, 1885,† that rapidly alternating currents confine themselves to the exterior of a conductor;‡ and Lord Rayleigh (*Phil. Mag.*, May, 1886) has developed an expression of Maxwell's so as to give the real resistance and inductance of a conductor for any frequency of alternation.

I propose to apply these considerations to the case of a lightning-flash.

A lightning-flash is the discharge of a condenser through its own dielectric, and is more analogous to the bursting or the overflow of a Leyden jar than to any other laboratory phenomenon. The condenser-plates may be two clouds, or they may be a cloud and the earth. The discharge occurs mainly through broken-down air, but a lightning-rod may form a part of its path.

The particular in which lightning transcends ordinary laboratory experiments is difference of potential or length of spark. The quantity of electricity is very moderate, the capacity of the condenser is quite small, but the potential to which it is charged is enormous. Flashes are often seen a mile long, and there is said to be a record of one seven miles long. Allowing 3,000 volts to the millimetre, a mile-long spark means a potential of 16 million electrostatic units.

The capacity of a condenser with plates a square mile in area and a mile apart is roughly about $\frac{2}{3}$ of a furlong, or, say, 10^4 centimetres.

The energy of such a condenser charged to such a potential is enormous, being over 10^{20} ergs, and there is no need to assume that so much as a tenth of this is ever dissipated in any one flash.

We may not be far wrong if we guess the capacity emptied by a considerable flash as about 10 metres, or one-thousandth of a microfarad. The total *charged area* is commonly much greater, but it is not all well connected, and it does not discharge all at once.

[The author proceeds to calculate the self-induction of the discharge under certain probable assumptions. We know first that the discharge will be of an oscillatory character§ if the total resistance of the path be not greater than L/S, L being the self-induction coefficient and S the capacity, or, as Mr. Heaviside calls it, the permittance. It is then shown that the critical resistance R_0 below which the discharge is oscillatory may be approximately expressed by

$$R_0 = 120 \frac{h}{b} \sqrt{\left(2 \log \frac{b}{a} - 1\right)} \text{ ohms} \quad . \quad . \quad . \quad (1)$$

where h is the height of the cloud, b the radius of the area which is discharged by the flash, and a the radius of the channel occupied by the flash. If the path is a metal rod, then a is the sectional area of the rod.]

And inasmuch as in practice h is likely to be much greater than b, and b much greater than a, this is a big resistance, which is not likely to be exceeded by the discharger. For if the line of discharge is a metallic conductor, a is moderate, but then so is R: whereas if the flash occurs through air, and it is not easy to say what the equivalent R is, then a must be considered extremely minute.

Suppose h to be a mile, b 50 metres, and a a millimetre; R_0 comes out about 15,000 ohms.

I think we shall be right in saying that this far exceeds any reasonable value that can be attributed to the resistance met with by a disruptive discharge. It is generally supposed, indeed, that

* Abstracted from the *Philosophical Magazine*, August, 1888.

† See also *Phil. Mag*, August, 1886, *et seq.*

‡ It is not possible, I think, to give Mr. Heaviside the credit of the original discovery of this theorem (though, doubtless, he discovered it for himself), for it had been virtually anticipated by so many persons. Not counting a wide general mechanical theorem of Sir William Thomson, which may be held to include this as a special case, a great part of it is clearly indicated by Clerk-Maxwell in his Paper in the *Phil. Trans.* for 1865. It then reappears in a more or less developed form in several Papers of Lord Rayleigh, specially perhaps that in the *Phil. Mag.* of May, 1882; and it is clearly stated for electrical oscillations in a spherical or cylindrical conductor by Prof. Horace Lamb (*Phil. Trans.*, 1883). There are also several papers by Oberbeck, the references to which I am unable to give just now. It is certain that all these philosophers had the data at command, and could at any time have constructed the completely explicit statement; but it may be held that none of their *actual* statements were quite so explicit as that of Mr. Heaviside in 1885. It is well known that some ingenious experiments of Prof. Hughes first excited public interest in the matter and quickened the mathematical abstraction into life.

§ The student may be referred to Dr. Fleming's exposition of this subject in *The Electrician* of May 11th, page 6.

Digitized by Google

a conductor and earth must have a resistance of only a few ohms, unless they are to form a considerable portion of the whole resistance a flash meets with.

[The author next shows that when the resistance of the path R is greatly less than R_0, the frequency of the oscillation is very great, "being usually something like a million a second more or less." But it has been shown by Lord Rayleigh* that with excessive frequencies of alternation, owing to the circumferential distribution of the current in the conductor, the resistance assumes a greatly modified value. If R be its ordinary amount, the new value R′ may be written

$$R' = \sqrt{\{\tfrac{1}{2} n h \mu R\}},$$

where n is the frequency, and μ_0 the permeability. Or, taking the permeability of the conductor the same as that of the space outside, this becomes

$$R' = \frac{1}{2u}\sqrt{(R R_0)}. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

Where $u^2 = \log \frac{b^2}{a^2} - 1$; the author believes that in practice u may be a number not greatly differing from 4 or 5. The actual resistance is, therefore, some fraction, something like, say, an eighth of the geometric mean of the ordinary resistance of the conductor and the critical resistance.

Under the same circumstances it is shown that the modified coefficient of self-induction L′ takes the form

$$L' = \mu h u^2 + \frac{R'}{n}.$$

But for very high frequencies the second term is negligible, and then L′ = L, or the normal value of the coefficient again holds good.

Now for condenser discharges, the impedance, instead of taking the sinusoidal form, or $\sqrt{(R'^2 + n^2 L'^2)}$, has the value $\sqrt{\left\{\frac{3}{4} R'^2 + \frac{L'}{S}\right\}}$. Here the second term is so much the larger that it is the only one that matters, and so

$$\text{impedance} = n L' = n L = n \mu h u^2 = \tfrac{1}{2} R_0 = \sqrt{\frac{L}{S}},$$

or

$$\text{impedance} = 60 \frac{h}{b} \sqrt{\left(2 \log \frac{b}{a} - 1\right)} \text{ ohms.} \quad . \quad . \quad (3)]$$

The total impedance, therefore, to a condenser discharge is half the critical resistance which determines whether the discharge shall be oscillatory or not; it has no important connection with the ordinary resistance of the conductor; neither does it depend appreciably on the magnetic permeability of its substance.

Hence, so long as the specific resistance of the conductor does not rise above a certain limit its impedance depends almost entirely upon the amount of space magnetised round it and upon the capacity of the discharging condenser, and is barely at all affected either by the magnetic permeability or the specific resistance, or even the thickness of the conductor. The one thing that does matter is its length. True, the diameter of the conductor does appear in the expression for impedance, but only under a logarithm; hence the effect of varying the thickness is only slightly felt.

Thus, then, we find that a lightning conductor offers an obstruction to a discharge as great as what a resistance of several thousand ohms would offer to a steady current of corresponding strength, the actual obstruction being given by equation (3).

Another way of putting the matter, is to say that for the first few oscillations the damping term, * * * has no appreciable effect; and that, accordingly, the E.M.F. applied to the conductor alternates rapidly from V_0 to $-V_0$ and back again.

But V_0 is the initial potential of the condenser, diminished (so far as the conductor is concerned) by the E.M.F. needed to jump whatever thickness of air it has jumped before reaching the conductor. Hence this V_0 may be something quite comparable to the potential needed to jump through air all the rest of the way, and it may depend on a mere nicety whether it prefers the conductor or not.

Thus arises the difficulty experienced in helping a jar to overflow by means of discharging-tongs brought near the two coatings. Sometimes the flash will make use of the tongs, sometimes it will prefer to go all the way through air; the fact being that the obstruction offered by a metal requires a large portion of the potential needed to break through a corresponding length of air. Undoubtedly the metal rod offers some advantage, but it is much less than has been usually supposed.

During the instant of discharge, therefore, the upper part of a lightning-rod experiences enormously high potentials in alternately opposite directions. Any conductors in the neighbourhood may easily receive side flashes, and even the bricks into which its supports are driven may be loosened and disturbed; and all this quite irrespective of any question as to the goodness or the badness of the "earth." It becomes, therefore quite a question whether it is not, after all, advisable to try and confine the discharge to the conductor by means of insulators, or whether it is better to reduce the excessive potential by lateral extensions of considerable static capacity. The advantage of sharing the discharge among a number of well-separated conductors, instead of concentrating it all in one, is obvious.

* *Phil. Mag.*, May, 1886.

Theory of Experiments on "Alternative Path."

In a lecture to the Society of Arts (see *Journal* of the Society for 22nd June, 1888, reprinted also in *The Electrician*, 29th June, 1888) I describe some experiments I have made on the E.M.F. needed to force a discharge through various conductors by seeing what length of air-space it will prefer to jump. The original potential of the condenser being able to jump, say, two inches without any alternative path, it remains able to jump, say, 1½in. when offered as an alternative a copper rod a quarter of an inch thick and six or seven yards long. This gives a rough notion of the kind of results obtained, and it shows that the extremities of the rod experience almost the whole of the original E.M.F. of the condenser.

Some experiments on much the same lines had been previously made by Prof. Hughes and M. Guillemin (see *Comptes Rendus*, 1886, *Annales Télégraphiques*, 1865,* Address to Society of Telegraph-Engineers, 1886); but they used a fine wire instead of an air-space, and tried what conductor would protect the fine wire from being deflagrated.

Under these conditions the experiment is practically a comparison between the impedances of two conductors, one of which has its inertia term the bigger, while the other has its resistance term the bigger. * * *

The complete solution for a case of divided-circuit condenser-discharge is by no means simple.

The experiment with an air-gap as the alternative path is better; because one may be sure then that *none* of the discharge chooses that path, when it is properly adjusted for its sparks just to fail.

Liability of Objects to be Struck.

There are also described in my lecture to the Society of Arts, above-mentioned, some experiments on the liability of objects to be struck. A distinction is drawn between two possible cases:—

(1) Where the air above the object is subjected to a steadily increasing strain till breakdown occurs.

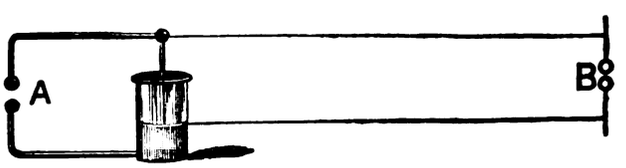
(2) Where the strain is thrown instantaneously upon air and conductors with a sudden rush.

In the first case the path is prepared inductively in the air, and the breakdown occurs at the place where the tension first reaches its limiting value; this is generally on a small knob or surface, and so this is struck and carries off all the discharge independently of its resistance. If its resistance is great the flash may be feeble; if its resistance is small the flash may be noisy; but the place of occurrence of the flash is not determined by these considerations. Glow and brush discharges from points and small surfaces may readily prevent any noisy flash from occurring.

The second case is different. When a sudden rush occurs the discharge shares itself among several conductors in proportion to their impedances, quite independently of any considerations of maximum tension or pre-arrangement of path by induction; so that no distinction is observable between points and large knobs in this case. Points cease to have any protective virtue; they can be struck by a noisy spark as readily as can a knob. The highest object will, in general, be struck most easily, provided its impedance is not very great. If it has a very high resistance it is barely struck at all, and it does not then protect the others.

Experiment of the Recoil Kick.

Among other experiments described in the lectures above-mentioned are some which appear to be of considerable theoretical



interest, wherein a recoil kick is observed at the ends of long wires attached by one end to a discharging condenser-circuit.

This diagram shows the arrangement.

The jar discharges at A in the ordinary way, and simultaneously a longer spark is observed to pass at B at the far end of two long

* *See* also a translation in *The Electrician*, July 13th, 1888, p. 305.

Digitized by Google

leads. Or if the B ends of the wire are too far apart to allow of a spark, the wires glow and spit off brushes every time a discharge occurs at A.

The theory of the effect seems to be that oscillations occur in the A circuit with a period

$$T = 2\pi\sqrt{(LS)},$$

where L is the inductance of the A circuit, and S is the capacity of the jar. These oscillations disturb the surrounding medium and send out radiations, of the precise nature of light, whose wave-length is obtainable by multiplying the above period by the velocity of propagation.

This velocity is known to be

$$v = \frac{1}{(\sqrt{\pi K})};$$

so the wave-length is

$$\lambda = vT = 2\pi\sqrt{\left\{\frac{L}{\mu}\cdot\frac{S}{K}\right\}}. \quad . \quad . \quad . \quad . \quad . \quad (4)$$

Now, $\frac{L}{\mu}$ is the electro-magnetic measure of inductance, and $\frac{S}{K}$ the electrostatic measure of capacity. Each of these quantities is of the dimension of a length, and the wave-length of the radiation is 2π times their geometric mean.

The propagation of these oscillatory disturbances along the wires towards B goes on according to the following laws :—

Let l_1 be the inductance per unit length of the wires ; let s_1 be their capacity, or permittance as Mr. Heaviside calls it, per unit length ; and let r_1 be their resistance per unit length.

Then, for the slope of potential along them, we have

$$-\frac{dV}{dx} = l_1\frac{dC}{dt} + r_1 C, \quad . \quad . \quad . \quad . \quad . \quad (5)$$

and for the accumulation of charge, or rise of potential with time,

$$-\frac{dV}{dt} = \frac{1}{s_1}\cdot\frac{dC}{dx}. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (6)$$

These are equations to wave-propagation, and will give stationary waves in finite wires of suitable length, supplied with an alternating impressed E.M.F.

The solution for a long wire, for the case when r_1 is small and the frequency big*, is

$$V = V_0 e^{-\frac{m_1 x}{n_1}} \cos n\left(t - \frac{x}{n_1}\right). \quad . \quad . \quad . \quad . \quad . \quad (7)$$

where $m_1 = \frac{r_1}{2l_1}$, and $n_1 = \frac{1}{\sqrt{(l_1 s_1)}}$.

The velocity of propagation is therefore n_1, and the wave-length is $\frac{2\pi n_1}{n}$.

Now, for two parallel wires, as in the figure,

$$l_1 = 4\mu\log\frac{b}{a} + \frac{r_1}{n},$$

and

$$s_1 = \frac{K}{4\log\frac{b}{a}},$$

while r_1 = the geometric mean between its ordinary value and $\frac{1}{2}n\mu_0$;

where the μ and K refer to the space outside the substance of the wires, μ_0 refers to their subtance, a is their sectional radius, and b their distance apart.

The second term of l_1 is, we have seen, practically zero for these high frequencies. Hence (n_1) the velocity of propagation of condenser-discharges along two parallel wires is simply the velocity of light, the same as in general space ; because $l_1 s_1 = \mu K$.

The pulses rush along the surface of the wires with a certain amount of dissipation, and are reflected at the distant ends ; producing the observed coil kick at B. They continue to oscillate to and fro until damped out of existence by the exponential term in (7). The best effect should be observed when each wire is half a wave-length, or some multiple of half a wave-length, long. The natural period of oscillation in the wires will then agree with the oscillation-period of the discharging circuit, and the two will vibrate in unison, like a string or column of air resounding to a reed.

Hence we have here a means of determining experimentally the wave-length of a given discharging circuit. Either vary the size of the A circuit, or adjust the length of the B wires, until the recoil spark B is as long as possible. Then measure and see whether the length of each wire is not equal to $\pi\sqrt{\left(\frac{L}{\mu}\cdot\frac{S}{K}\right)}$.

I hope to communicate some numerical results of observations made in this way to the British Association Meeting at Bath.

It is interesting to see how short it is practically possible to make waves of this kind. A coated pane can be constructed of, say, two centimetres electrostatic capacity, and, by letting it overflow its edge, a discharge circuit may be provided of only a few centimetres electro-magnetic inductance. Under these circumstances the radiated waves will be only some 20 or 30 centimetres long, corresponding to a thousand million alternations per second. Some beautiful diffraction experiments have been described by Lord Rayleigh in a recent Friday evening discourse to the Royal Institution (reprinted in *Nature*, June, 1888), and some of these might be used to concentrate the electro-magnetic radiation upon some sensitive detector—possibly one of Mr. Boys's radio-micrometers, more likely some chemical detector—some precipitate or other that can be shaken out of solution by the impact of long waves, or some of Captain Abney's photographic agents.

Certainly the damping-coefficient R/2L is high, and the radiation has a very infinitesimal duration ; but a rapid succession of discharges can be kept up by connection with a machine.

No doubt much shorter waves still may be obtained by discarding the use of any so-called condenser, and by causing the charge in a sphere or cylinder to oscillate to and fro between its ends, as might be done by giving it a succession of sparks. These oscillations, it is to be feared, however, would have too small energy to be detected by ordinary means. If they could be made quick enough to affect the retina, no doubt we could detect them with the greatest ease ; but it is manifest that this can only be done by reducing the circuit to a size less than the wave-length of light. The wave-length of the electrical radiation is six times the mean of the inductance and capacity, and each of these quantities is very comparable with the linear dimensions of the conductor concerned. By setting up electric oscillations in a body as small as a molecule no doubt they would be rapid enough to give ordinary light-waves, but the probability is that this is precisely what light-waves are.

Either the atoms are made to vibrate relatively to the æther, by the effect of heat, and so to produce radiation ; or else electrical oscillations are set up in comparatively quiescent atoms, not by heat but by the impact of radiation from other sources, or by some organic process set in play by living protoplasm.

It is thus I would seek to explain phosphorescence and other direct production of light from cold sources.

This direct production of light we have not yet learned artificially to accomplish ; we can only heat bodies and trust to their emitting light in some unknown manner as a secondary result ; but the direct process has been learnt by glowworms and Notilucæ, and it is for us, I believe, one of the problems of the immediate future.

University College, Liverpool, July 7, 1888.

Postscript.—Since writing the above I have seen in the current July number of Wiedemann's *Annalen* an article by Dr. Hertz, wherein he establishes the existence and measures the length of æther waves excited by coil discharges ; converting them into stationary waves, not by reflection of pulses transmitted along a wire and reflected at its free end, as I have done, but by reflection of waves in free space at the surface of a conducting wall.

My friend Mr. Chattock has also written to me about a recent experiment exhibited to the Physical Society, I do not know by whom, which shows that the same discharge as can excite æther waves a kilometre long, can excite air waves of one millimetre. The whole subject of electrical radiation seems working itself out splendidly.

Cortina, Tyrol, July 24th, 1888.

* Mr. Heaviside has treated the problem in a much more general manner, see *Phil. Mag.*, 1888, especially February, 1888, p. 146.

BOOKS, &c., RECEIVED.

"Our Cable Communications." By. S. VYLE, Government Electrician. (Reprinted from *Timehri*, the Journal of the Royal Agricultural and Commercial Society. Georgetown, Demerara.)

"Éléments et Méta-Éléments." Translation of a Paper read before the Chemical Society of London by Mr. Crookes, F.R.S. (Paris : Gauthier-Villars et Fils.)

MESSRS. ELWELL-PARKER'S EMPLOYÉS.—On Saturday last the workpeople of Messrs. Elwell-Parker (Limited), Commercial-road, Wolverhampton, including the electricians, clerks, and draughtsmen, to the number of over 200, held their annual excursion at Bridgnorth. Mr. Thomas Parker (managing director) and Mr. Walton (secretary) were present. Mr. T. Parker, in responding for the firm, said it seemed that the confidence of the people in electricity was being gained, and it needed no prophet to see that the beginning of the prosperous days of electricity were not far distant.

The Electrician.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial and Publishing Offices
No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.
Telephone No. 2714.

All Communications to be addressed to "The Electrician," 1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to "The Electrician."

All letters intended for insertion in "The Electrician," or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.

"The Electrician" is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.

"The Electrician" is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained at all Booksellers and Newsvendors; or direct from the office as above.

SPECIAL NOTICE.

Owing to the increase in the number of pages of "The Electrician," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows :—

	3 months.	6 months.	12 months.
For Foreign Parts and Colonies :—	s. d.	s. d.	s. d.
Within Postal Union	6 6	... 12 6	... 24 0
„ Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	... 14 6	... 28 0
The rates for the United Kingdom remain as follows :—	5 0	... 10 0	... 19 6

TO ADVERTISERS.

"The Electrician" offers exceptional advantages to Advertisers. **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to this office.

Advertisements intended for the current issue must be handed in not later than 4 p.m. on Thursday.

TECHNICAL PRINTING.

"The Electrician" Printing and Publishing Company (Limited) *beg to inform Electricians and Electric Light Engineers that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

The Electricians' Directory.

Royal 8vo. Cloth Boards, 3s. 6d. Boards, 3s.

At the end of December in each year is issued The Electricians' Directory and Handbook. *The Directory was established in 1883, and has now attained considerable proportions. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, accompanied in many cases by Portraits.*

THE DIRECTORY FOR 1889 IS IN PREPARATION.

CONTENTS OF THE CURRENT NUMBER.

"THE ELECTRICAL WORLD" IN THE UNITED KINGDOM.

Arrangements have been made by which "The Electrical World" of New York can be obtained from "The Electrician" Office, 1, Salisbury-court, Fleet-street, London, E.C.

The Rate of Subscription (payable in advance), including postage, is **£1. 1s. 0d.** *per annum to this Country and Abroad.*

Single Copies of "The Electrical World" can also be obtained, **price 6d. each.**

The Rates for Advertisements in "The Electrical World" of New York can be obtained on application to "The Electrician" Printing and Publishing Company, Limited, as above.

"THE ELECTRICIAN" IN THE UNITED STATES.

Similarly, "The Electrician" can be obtained in America at the Offices of "The Electrical World," 168 to 177, Potter-building, New York.

"The Electrician" can also be obtained from D. Van Nostrand, *23, Murray-street, and 27, Warren-street, New York.*

The Rate of Subscription for American Subscribers (payable in advance) is $6 per annum.

W. T. Bottomley (Dublin) and Others.—*We shall be glad if you will let us know the names and addresses of the newsagents from whom you procure your copies of "The Electrician." Steps will at once be taken to determine the legal responsibility of persons who insert objectionable leaflets in our journal. We need not assure our readers that it is done without our consent, and in spite of our repeated complaints.*

SCIENCE IN COURTS OF JUSTICE.

So much of the valuable time of the Courts of Justice lately has been taken up with law suits relating to rival inventions that something very like a scandal has been created, and suggestions are being freely made to prevent the growth of an evil which readers of the legal reports in this journal will readily admit is seriously on the increase. A recent article in our contemporary *Nature* has drawn attention to the subject with becoming dignity and impartiality, and with a knowledge of its legal bearings which can hardly fail to exert some influence on all future litigation of the kind under discussion. With its concluding observation, everyone, we take it, will entirely agree : "The orderly and effective administration of justice, the weight which should be attached to judicial decisions, the economy of

Digitized by Google

public time, and we would add, the self-respect of scientific men, and the best interests of scientific discovery, all call loudly for some . . . . . reform;" and after careful consideration of *Nature's* suggestions we think it is entitled to say "some such reform as that here suggested."

Briefly stated the proposition is, that the Court shall either make use of the power conferred upon it by the Judicature Act of 1873 to refer the matter in dispute to an umpire or referee; or else that it shall follow the practice of the Admiralty Court, which, on the application of one of the parties to the suit, can call in two Elder Brethren of Trinity House to assist the judge in trying the case. We want, in fact, "sworn scientific assessors in courts of justice to aid unscientific judges in arriving with reasonable despatch at reliable conclusions on matters which demand scientific knowledge." Our contemporary leaves us in little doubt as to which of the two methods would be most satisfactory. For our own part we have no hesitation in expressing a decided preference for the sitting of experts by the side of the judge, a practice which is permitted and generally adopted in what are called Admiralty cases; and we will give our reasons presently. But of course there would be no need to adopt either of these plans if our Patent Laws were framed so that they could be administered judicially. They are, on the contrary, so framed as almost to provoke or invite litigation, while providing no means of settling disputes except in a court of justice which possesses none of the technical knowledge essential to a proper adjudication upon them. As a rule the judge is in the position of Mr. Justice KAY, who, on a recent notable occasion, admitted that he had not had the requisite scientific training to try the case brought before him; and although the event showed that it could not be said of him, it may as a rule be said of most judges that they are at the mercy of the scientific witnesses, who are not slow to instruct the judge in the learning which he lacks. The astonishment created by Mr. Justice KAY's aptitude for learning is proof of its being a quite phenomenal exception to the rule.

It is beyond hope, however, to get the Patent Laws reformed so that the Patent Office shall itself interpret the documents for which it assumes responsibility; and we turn to the other methods of procedure as being the more feasible and attainable. It appears that the committee to which Mr. Justice KAY referred a crucial point in the Edison-Swan *versus* Brush case was in conformity with the powers granted under the Judicature Act already mentioned; and the question naturally arises, Why should he not have referred the main points to them at an early stage of the proceedings? By doing so probably two-thirds of the twenty-one days of the Court's time would have been saved. With the President of the Royal Society as moderator the decision might have been conclusive and final on the whole of the technical points at issue. But we could not count on such an arrangement for every case; and it may be feared that any selection the judge might make of expert referees would be open to objection on the score of their being interested directly or indirectly in the result. Again, it is, we believe, a common experience of litigants who have had their cases sent to umpires or referees that both parties come out dissatisfied. These dignatories are not bound by the strict rules which prevail in the higher courts; and are apt to take a Roger de Coverley view of their functions, namely, to arbitrate rather than adjudicate, there being "a good deal to be said on both sides."

Now, what is wanted above all things is a decisive ruling in cases involving the validity of a patent. A specification either means what the patentee alleges of it or it does not; and there is rarely any room for compromise. A court of justice is pre-eminently the place to try the question, which is mainly one of fact; and when the difficulties of interpreting language have been got over, the legal training of a judge is the best guarantee for a perfectly sound decision. These difficulties, it seems to us, would be easily overcome by following the practice of the Admiralty Judge, who is assisted by two nautical assessors, and who uses their knowledge on all technical evidence, but delivers his judgment independently of them. According to the writer in *Nature*, the 56th section of the Judicature Act of 1873 empowers the High Court or Court of Appeal to call in assessors; and if this be the case there is no reason why the usage of the Admiralty Court should not be followed by the other courts. It is greatly to be hoped that when the next technical dispute is carried to a court of law the litigants will agree to put this legal question to the test. Both parties would be gainers by the enormous saving of time and expense which the presence of scientific assessors would ensure, and no one would lose anything by having his claims listened to by a competent tribunal.

Procedure under these conditions would very likely reduce the number of cases brought up for adjudication; but even patentees may be thankful to have the temptation removed of trying their luck before a non-scientific judge. Patent causes are at present very much in the nature of a lottery, and it is no wonder there are so many of them. There would be fewer if the element of chance were considerably reduced by increasing the competency of the Court. The objection to expert referees apart from the Court would apply with less force to expert assessors sitting all through the trial. Their judicial function would be more pronounced, and the judge might be trusted to weigh their partiality if they betrayed any. What a vast amount of forensic pleading would the Court be spared at the very outset! and what a still vaster amount of technical evidence would be withheld if this practice were adopted! It would be no longer necessary for counsel to instruct the judge; nor would scientific witnesses then venture to hoodwink or to lecture him. We are not disposed to speak too hardly of either counsel or witnesses in these cases. The situation is one which offers direct encouragement to a display of superior knowledge, if not of downright partisanship. For the credit of scientific witnesses, as well as in the interest of justice, a form of procedure such as our contemporary has recommended for technical law suits is much to be desired.

ELECTRICAL TRACTION ON THE INNER CIRCLE.

BY S. EVERSHED.

Ever since the possibility of an economical system of electrical transmission of power became apparent to engineers, the application of electrical traction to railways has been regarded as only a question of time. One railway in particular has always seemed to suffer for want of some economical method of working by which steam locomotives would be dispensed with. In these circumstances it is remarkable that so little progress should have been made during the past ten years. Electrical engineers who deplored the severe check given to their industry by Chamberlain's Act seem to have been unable to divert their stifled energy into a new channel where no oppressive legislation barred the road to success. The reasons for their want of activity are not far to seek, the financial question alone forming an almost insuperable difficulty where steam locomotives are already in use. On the Underground Railway, however, the imperative necessity of dispensing with steam at almost any cost is becoming more apparent every day.

When the chairmen of the Metropolitan and District Railways have settled their microscopic differences, and have arranged so to work their lines as one system, then, and not

Digitized by Google

until then, the engineering world may be called upon to apply electrical traction on the Inner Circle line. How will it be done? The ways in which this question will be answered will differ only in detail, since the broad outlines of all strictly engineering schemes would be alike. The writer proposes to discuss here only those points which would be common to every system, entering into details only where such details are of vital consequence. Perhaps it is as well to warn the reader who expects to be introduced to a novel or original idea that he will be disappointed.

The comment just made on the inactivity of electrical engineers should have been made with a reservation in favour of the advocates of the "accumulator" system, who have always been remarkable for their energy and their faith in the system. The writer is a little uncertain whether a recently-advertised scheme is to be taken seriously as another manifestation of the all-devouring promoter, or charitably as a sublime instance of "fools rushing in." In either case it seems desirable to ascertain just what the scheme involves.

The whole world knows that an electric locomotive is being built for use on the Underground Railway; it is to "take its turn regularly with the steam locomotives on the line;" its working expenses are only to exceed those of the present engines by an insignificant amount; it is to carry accumulators sufficient for two trips round the Inner Circle; and although the present engines are said to be 450 horse-power, the electric motor is to be capable of working up to 600 horse-power.

Let us examine this statement in detail. The most efficient secondary cell at present in the market has a normal output of about 100 watts, with a weight of 240lb, but these cells will give 200 watts for a short time without injury to the plates; put it at 250 watts, or one third of a horse-power.

Taking 600 horse-power to mean electrical horse-power at the motor terminals, the motor car will have to carry $600 \times 3 = 1{,}800$ cells! The cells to be used are, however, no doubt of a *much-improved* type, and probably not more than two-thirds the dimensions of the cells now in the market; but even if we reduce each cell to $1\frac{1}{2}$ cubic feet they would, if put in a row, extend some 600 yards. 2,700 cubic feet implies a box 14ft. each way, packed full of accumulators. The imagination reels at the thought of such a tumulus of lead and acid rushing round the Inner Circle.

Those accumulators which are within the writer's limited experience weigh approximately 120lb. per cubic foot when the cells are packed in close order, and any improvement in the direction of increased output and durability would probably increase the weight per unit volume. Let us be merciful, and put down the weight at only 100lb. per cubic foot—alas! the tumulus will weigh 120 tons.

The timid shareholder will want to know what all this is going to cost? The present price of accumulators may be taken at £40 per horse-power, but as the motor's cells are to be worked at $2\frac{1}{2}$ times the normal rate they may be put at £16 per horse-power, or a total of $600 \times 16 = £9{,}600$. The makers ought to allow a liberal discount to a customer using cells on such a colossal scale, and it is only reasonable to deduct 50 per cent. from the account, and let it stand at £4,800. It may be remarked in passing that a heavy tank-engine costs from £2,500 to £3,000.

One of the charms of the "system" is that the wages of one stoker are saved on each train; on the other hand, maintenance of the tumulus at 10 per cent. = £480 = 7 stokers. Again, we must allow 3 battery men to look after 1,800 cells, and if we write 3 battery men = 3 stokers we have a net *increase* of 9 stokers per train! These locomotives being made of sufficient capacity for two trips, or one and a-half hour's actual work, the cells will presumably require at least two hours for recharging (a daily paper, noted for its scientific propensities, puts the time for recharging at ten minutes!), and consequently each steam locomotive will be replaced by *two* electrical ones; or, to be exact, there must be two sets of cells per train, which brings the capital account to £9,600 and the depreciation account to £960 per annum per train.

The only reasonable quantity in the whole scheme is the coal consumption, for, take 1·5lb. per 1 horse-power-hour as the consumption of the fixed engines, ·7 as the efficiency between I. h.-p and E. h.-p. at dynamo terminals, ·7 again for accumulator efficiency, ·9 for motor, and ·8 for gearing, and the consumption works out at about 4lbs. per horse-power delivered to the wheels, a consumption which probably does not differ much from that of the present engines.

It is stated that the engineers of the scheme have had some difficulty about working the vacuum brake. It is a difficulty. A store of vacuum is required to work the "plain vacuum" brake, unless an electric ejector is at hand; but why not try the locomotive on a District train using the non-automatic Westinghouse brake, requiring a small pump and a reservoir of a few cubic feet capacity on the locomotive? It would be a pity to delay the trials for such a trifle as want of brake-power when the horrible doubt is rising in some sceptical minds, "Will a brake of any kind ever be required on that locomotive?"

To sum up. It is proposed to employ an electric locomotive costing over £9,000, weighing over 100 tons, and requiring one driver and the equivalent of nine stokers to work it, to say nothing of the charging plant. Clearly the accumulator system is not in the category of the strictly engineering schemes which we set out to discuss.

Although the advantages of electrical traction on an underground railway are obvious, the conditions necessary for its successful application to the Metropolitan Railways are not too well understood. The conductor system of electrical traction is working successfully wherever it has been carried out rationally. No difficulty on this score is likely to be felt on the Inner Circle. Again the gearing problem has received many more or less successful solutions, and the difficulties met with on the Inner Circle will be those arising from the application of apparatus hitherto used only on a small scale to the necessities of a full grown railway on which the traffic is at times exceptionally heavy.

The Inner Circle will probably be worked electrically long before the numerous extensions are able to dispense with steam. The managers will have to choose between the present system of running trains from the city to the suburbs—in which case steam locomotives must take the electrical trains, motors and all, over the extensions—and running separate extension trains from the points of junction with the Inner Circle, and introducing a frequent service of light electric trains on the Circle itself. The writer is inclined to think the public would soon find the disadvantage of changing at the junctions outweighed by the gain from greater punctuality and quickness consequent on the adoption of the latter system, there being nothing to interfere with the absolute regularity of the Circle trains. To ensure popularity, the number of the new Circle trains must be at least as great as the total number of trains on the line at present. If 28 trains are put on each rail they will run half a-mile apart (the length of the Circle being 14 miles), and at the present speed of 12 miles per hour, inclusive of stops, the trains will follow each other at intervals of $2\frac{1}{2}$ minutes. The inner and outer rails will require the same number of trains on an average taken over a whole day, so that motive power must be provided for something more than the average requirements of 56 trains. But the discussion of the correct basis for the calculation of the total power required must be reserved until the maximum and average power required per train are determined.

Each train might be made up of four light cars of a similar type to the bogies used by the Metropolitan Company, but of lighter construction; the present rolling stock seems needlessly heavy for speeds which average 15 miles per hour. The dead weight of modern passenger stock often amounts to as much as ·4 ton per passenger, and is seldom less than half this amount, whereas in tramcars the dead weight does not usually exceed ·05 ton per passenger, or perhaps ·1 ton where no outside passengers are carried. Now, although tramcars are designed for one-half the speed of the underground trains, the hard and uneven road bed over which these light cars run must subject them to far more serious strains than are experienced on the elastic and comparatively even permanent way of such a line as that under consideration. The writer will, however, assume the cars to weigh ·2 ton per passenger. A train should be capable of seating at least 300 passengers

Digitized by Google

(some of the present trains would carry nearly 400), so that the dead weight, exclusive of motors and gear, will be 60 tons. The mean passenger may be put down at ·06 ton, the maximum live load being 18 tons. If 10 tons are allowed for motors and gear the whole train weighs 88 tons. It will be safe to provide power for 100 tons.

Each train has to perform the following cycle every 2½ minutes:—20sec. stopping at station, 20sec. to reach full speed of 15·6 miles per hour, 100sec. run at this speed and 10sec. to bring the train to a stand at the next station—a total of 150sec., or 2½ minutes. The maximum work done is during the 20sec. allowed to reach full speed, and is made up of the work stored as momentum + work done against friction + work done against gravity. The energy is stored at the rate of $\frac{100 \times 23^2 \times 3}{2 \times 32 \cdot 2} = 2{,}470$ foot-tons per minute, or about 168 horse-power.

Tractive resistance at low speeds is about 10lb. per ton, to which 5lb. should be added for curves, which are the rule on the Inner Circle, and the work done in overcoming friction is therefore $\frac{100 \times 15 \times 230 \times 3}{33000} = 31 \cdot 4$ h.-p. Lastly, to start up a gradient of 2 per cent., say, requires $\frac{100 \times 2240 \times 4 \cdot 6 \times 3}{33000} =$ 93·5 h.-p.

Thus for $\frac{1}{2} M v^2/t = 168$ horse-power is wanted.

„ friction = 31·4 „ „

„ gravity = 93·5 „ „

Total.....292·9

We will put this figure at 300 horse-power. This, then, is the maximum power a train will require when starting with full load up a heavy gradient and round a sharp curve. It is not the actual maximum which the train motors will be required to develop, however, as no allowance has been made for the static friction at starting, but as the effort to overcome it lasts for a fraction of a second only, it is more a question of the mechanical strength than of the output of the motors.

(To be continued.)

REVIEWS.

Applications of Dynamics to Physics and Chemistry. By J. J. Thomson, M.A., F.R.S. (Macmillan and Co., 1888.)

The author states in his preface that this work contains the substance of a course of lectures delivered at the Cavendish Laboratory in 1886, together with an account of some of his later investigations. A considerable portion of it consists of a systematic treatment of a series of researches, parts of which have been published in the *Philosophical Magazine* and in the *Transactions* of the Royal Society during the last few years.

The most important of these were the Papers published in the *Transactions* of the Royal Society for 1885 and 1887, which, dealing as they do with phenomena lying on the borderland between different departments of physics and between physics and chemistry, have hitherto been to a great extent neglected both by physicists and chemists. The principal object which the author has kept in view throughout has been to develop methods of applying the general principles of theoretical dynamics to the investigation, from purely experimental data, of the relations between various physical phenomena. He has succeeded in doing this for a large number of series of phenomena, showing them to be related to other phenomena in such a manner that the existence of either implies the existence of the others, quite independently of the explanations which may be given of them.

The general principle of the methods adopted consists in expressing the properties of a physical system in terms of a single function of quantities, fixing the state of the system. The method, due to Lagrange, was employed by Clerk Maxwell, in his Paper on "The Electro-Magnetic Field," and is extensively used in his "Treatise on Electricity and Magnetism," and it was applied to thermo-dynamic phenomena by Prof. Willard Gibbs, in his Paper on the "Equilibrium of Heterogeneous Substances."

This function, which has been called the Lagrangian function of the system, is a function of the energy of the system expressed in terms of the variables, equal in number to the number of degrees of freedom of the system, which determine its configuration at any instant, and of the velocities or the momenta corresponding to these variables.

The Lagrangian function assumes its simplest form when the kinetic energy is expressed in terms of the variables, or co-ordinates, and their velocities only, and is then equal to the difference between the potential and the kinetic energies of the system.

The author classifies the different phenomena to be considered into—

1. Reversible vector phenomena.
2. Reversible scalar phenomena.
3. Irreversible phenomena.

In the first class, which include the relations between most of the phenomena of elasticity, electricity and magnetism, the co-ordinates are to a greater or less extent under control, and may be made to assume any values within certain limits.

When scalar quantities such as temperature are involved, the phenomena depend on a multitude of co-ordinates over the individual motion of which no control can be exercised, though their average motion may be controlled to some extent.

In ordinary dynamics the configuration of a system is completely fixed by means of the co-ordinates; but this is not always the case for physical systems; Thomson and Tait have shown, however, that if the kinetic energy of the system can be expressed without certain of the co-ordinates, these co-ordinates may be ignored, and the system may be treated as if it were fully determined by the co-ordinates, in terms of which, together with their differential coefficients, the kinetic energy is expressed.

When the co-ordinates have been chosen the Lagrangian function may be written down in its most general form in terms of these co-ordinates and their differential coefficients. The physical consequences of the existence of each term are then considered, and if any of these are in contradiction with experience it is concluded that the corresponding term does not exist in the expression for the Lagrangian function. Another method of proceeding, which, however, is only applicable to the first class of phenomena, is to take a certain term which experimental results show must exist in the expression for the Lagrangian function, and to develop the consequences of its existence.

When the expression for the Lagrangian function has been simplified as far as possible in the case of any given system the author makes use generally of Lagrange's general dynamical equations, or of Hamilton's principle of varying action, for the investigation of its properties.

In the case of phenomena into which scalar functions enter the value of the Lagrangian function cannot be determined for any given moment, as the mean value only of some of the co-ordinates is known. The mean value of the function is therefore calculated, and as it is shown that for a system in dynamical equilibrium—that is, one in which the motion is steady—the Lagrangian function has a stationary mean value, the conditions of equilibrium of the system can be investigated by applying the methods of the calculus of variations to the mean Lagrangian function.

The portion of the book devoted to the consideration of phenomena which depend entirely or partly on scalar functions will probably, on account of the comparative novelty of the methods employed, excite the largest amount of interest, but some of the author's conclusions in this part of the work appear to us to rest upon somewhat dubious assumptions, and some of his experimental data are, in our opinion, not sufficiently well established for the conclusions based upon them to be accepted without further confirmation. Even in these cases,

Digitized by Google

however, the methods employed are most interesting and suggestive, and as the sources from which the data are taken are invariably indicated, the reader will be able to form his own opinion of their value. It will be impossible within the limits of a review to do more than give a few examples of the results obtained, but these may perhaps help to induce those of our readers whose mathematical training has been carried beyond the elementary stage to obtain the book and study it for themselves. If they do so they may rest assured that they will not regret the time spent on it; and even if they are not mathematicians they will find a mass of information of great interest which otherwise they could obtain only by extensive search through recent scientific literature, together with numerous suggestions of subjects for experimental research.

Wiedemann has shown (*Electricität*, Vol. III., p. 689) that when an electric current flows along a longitudinally magnetised wire it produces a couple tending to twist the wire. The consideration of the term in the Lagrangian function indicated by this phenomenon shows that when a longitudinally magnetised iron wire is twisted an E.M.F. will be produced which will last as long as the twist is changing, and any alteration in the longitudinal magnetisation of a twisted iron wire will produce an E.M.F. lasting as long as the magnetisation is changing. The former result has been experimentally verified. The second result shows that Faraday's rule that the E.M.F. round a circuit due to induction is equal to the rate of decrease in the number of lines of force passing through it will not apply to the case of a twisted iron wire, for an E.M.F. might be produced by moving it in the plane of the magnetic force.

It is shown that if the electromagnetic theory of light is true the existence of the Hall effect leads to the result that a circularly-polarised ray of light must produce a magnetic force in the direction of its propagation, but the amount would be too small to be detected experimentally.

Some recent experiments made by Mr. Cassie in the Cavendish Laboratory have shown that the specific inductive capacities of glass and some other dielectrics increase with the temperature, from which it is shown to follow that a piece of glass will be cooled when it moves from a place where the electric force is weak to one where it is strong.

The numerical value of the increase in the case of glass leads to the result that at a temperature of 30°C. the mechanical equivalent of the heat absorbed by a Leyden jar while being charged, if its temperature remains constant, is about two-thirds of the work supplied to it from electrical sources.

A very important result pointed out by the author is that in the case of a thermo-electric circuit the consideration of the heat developed can only give information about the part of the E.M.F. which depends upon temperature, from which it follows that the Peltier effect can throw no light on the absolute difference of potential between two different metals, and therefore that there is nothing in the phenomena of thermo-electricity to lead to the conclusion that the large difference of potential observed by Volta between two different metals in contact is due to chemical action between them and the surrounding medium.

By the consideration of a dynamical analogue to a twisted wire, it is shown that Dr. Hopkinson's experiments on the residual charge in glass prove that glass cannot be homogeneous, but must be composed of a mixture of different silicates.

Blake has shown (Wiedemann's *Electricität* Vol. IV., p. 1,212), that the vapour proceeding from an electrified liquid remains unelectrified. The consideration of the mean Lagrangian function of a liquid and its vapour in contact with each other shows that this experiment proves that the effect of electrification will be to diminish the vapour density, for which there is equilibrium between the liquid and the vapour, and so to increase the tendency of the vapour to become condensed. An electrified drop of rain would therefore be expected to be larger than an unelectrified one, a conclusion which is well known to be in accordance with experience. The influence of dissolved salts and gases on the vapour pressure is also considered, and there is an interesting discussion of the experimentally-observed properties of dilute solutions.

The chapters devoted to the consideration of chemical dissociation, of the general theory of equilibrium, including the theory of mass actions, and of the influence of the physical conditions on the coefficient of chemical combination, are of exceptional interest, as they mark another stage in the slow, but sure advance which is being made in the application of mathematical analysis to the explanation of chemical phenomena, which we have every reason to hope will in time enable chemistry to definitely take up its position as a branch of dynamical science.

The existence of surface tension in gases, for which there is some experimental evidence, leads to the conclusion that in general gaseous chemical dissociation will be facilitated by increasing the free surface of the gas, which would afford an explanation of the manner in which chemical reactions between gases are facilitated by their absorption by such substances as charcoal or spongy platinum.

As the magnetic properties of solutions are very feeble, except in the case of salts of iron, magnetism cannot be expected to have any sensible effect on chemical action except for these salts. In the case of solutions of iron, however, such effects have been observed; for example, when a solution of copper sulphate is placed on an iron plate, copper is deposited and iron dissolved, and if the plate is placed over the poles of a strong electro-magnet, the copper deposit is found to be thinnest where the magnetic force is most powerful—that is, over the poles. The consideration of the Lagrangian function of a magnetic solution leads to the result indicated by experiment, and it can also be shown that any chemical action which produces an increase in the coefficient of magnetisation is hindered by the action of magnetic forces.

If a solution of a salt is placed in a non-uniform magnetic field, it can be shown that if the coefficient of magnetisation increases with the strength of the solution, as is the case for iron salts, the magnetic force will tend to drive the salt from the weaker to the stronger portions of the magnetic field, so that the strength of the solution will be the greatest where the magnetic force is most intense.

A chapter is devoted to the consideration of change of state from solid to liquid, and it contains an interesting discussion of experimental results. The chapter which follows this, and treats of the connection between E.M.F. and chemical change, contains a valuable discussion of the theory of Grove's gas battery, together with some interesting and useful results respecting the relations between E.M.F. and temperature for batteries in which dilute solutions are employed.

The book concludes with a chapter on irreversible effects. The author reminds us that on the assumption that the properties of matter in motion, as considered in abstract dynamics, are sufficient to account for all physical phenomena, the irreversibility of any system must, as was first pointed out by Maxwell, be due to the limitation of our powers of manipulation.

The author then points out that just as we are unable to manipulate very minute portions of matter, so our senses are unable to separate events which follow in very rapid succession, so that we are at liberty, if convenient for purposes of explanation, to treat any phenomenon as the average effect of a series of rapidly changing phenomena of a different kind. He applies this to the explanation of electric resistance, and the consideration of the results of recent experimental investigations leads him to the conclusion that the passage of an electric current is really due to a series of discharges due to the splitting up of the molecules of the conductor. He adduces among other results in favour of this view Dr. Schuster's discovery that the electric discharge passes with great difficulty through mercury vapour, which is supposed to be a monatomic gas, and also the discovery of Hertz, which has recently been noticed in our columns, that the passage of the electric discharge through a gas is facilitated by exposing it to the action of the violet or ultra-violet rays, which, as is well known, have a strong tendency to split up the gaseous molecules. It is pointed out that the experimental evidence tends to show that when the E.M.F. is small the splitting up of the molecules takes place independently of it, but that in case of larger E.M.F.'s the E.M.F. itself assists this splitting up of the molecules.

The differences between metallic and electrolytic conduction

Digitized by Google

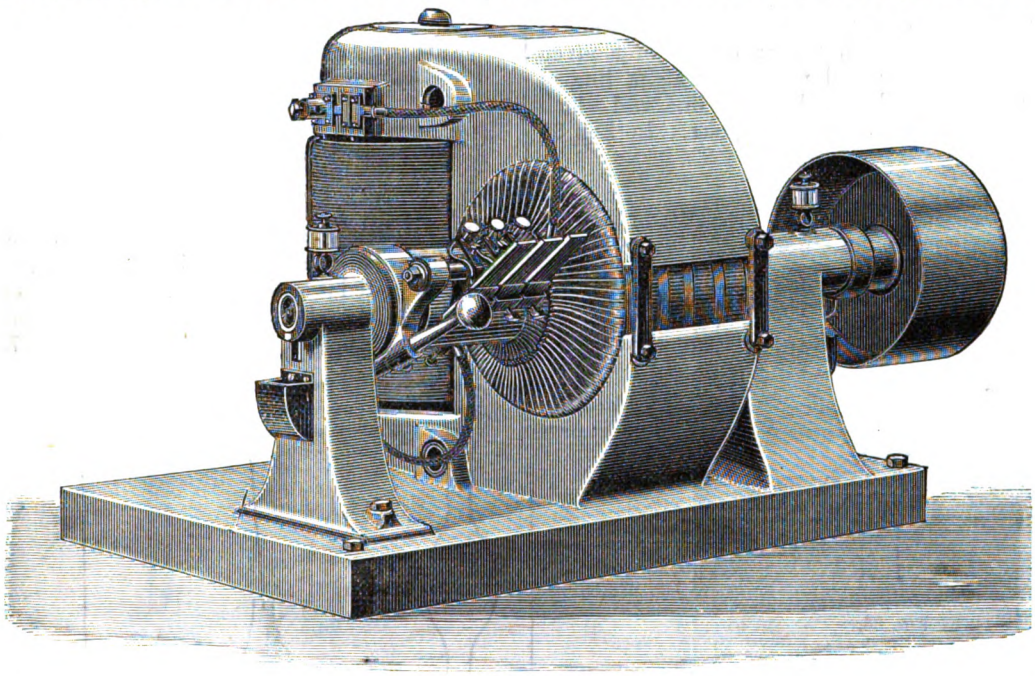
he considers to be merely differences of degree, and to be due to the vastly greater number of molecules taking part in the former. This theory of electrical conduction is shown to give an explanation of the general correspondence between the electrical and thermal conductivities of the metals, and appears to be in accordance with the most recent views on electrolysis.

We cannot conclude without recording our opinion that this work of Prof. Thomson's forms a most noteworthy and important contribution to the literature of mathematical physics and chemistry.

THE "LEEDS" DYNAMO.

In our recent account of the Cadogan Electric Light Company's Central Station, at Chelsea,* we mentioned that the "Leeds" dynamo is employed. As this machine is, perhaps, scarcely as well known as it deserves to be, we give the following additional particulars with which the makers have kindly supplied us :—

The "Leeds" dynamo is manufactured by Messrs. Greenwood and Batley (Limited), of the Albion Works, Leeds.



The "Leeds" Dynamo.

From the adjoining illustration, it will be seen that the field-magnets are of the single horseshoe type, the core of which, placed between the two pole-pieces, forms at the same time the yoke of the magnet. The magnet core is made of specially prepared wrought iron of the best and softest quality, carefully annealed. The massive pole-pieces are made of soft cast iron, and of a form and proportions which have been found in practice to give great steadiness in the magnetic field. The magnetic circuit, it will be noticed, is made as short as possible. The lower pole-piece and bed-plate of the machine are cast in one piece.

The armature is of the cylinder type, with Gramme connections, and is wound with carefully insulated wire. The core of the armature is built up of thin annealed charcoal iron discs, insulated from each other and firmly mounted on the shaft.

The armature has a large cooling surface and thorough internal ventilation. The armature shaft is of Bessemer steel, and revolves in long bearings of special white metal, provided with sight feed lubricators.

The commutator is made of a special metal which is said to possess very great durability. The segments (into one end of which the armature connections are securely soldered) are well insulated with mica plates ; being of a large diameter and great length, the commutator provides a maximum of wearing surface.

The brushes are adjustable in all directions, and the pressure on the commutator is regulated by springs ; the brush holders are provided with an arrangement for maintaining an even pressure of the brushes on the commutator, and also with thumb screws for keeping the brushes from making contact when not in use. The brush holders are attached to a rocker, which is free to move in either direction, backwards or forwards, according to the lead required, and can be readily locked in any position.

The electrical connections outside the machine, as may be seen, are simple and convenient; they are mounted on fibre and attached to the main frame at the most convenient place. All the materials employed are of the best quality, and the workmanship is of that high excellence for which the firm of Messrs. Greenwood and Batley are so well known.

The electrical efficiency of these machines is given as 93½ per cent., which is very high for machines of this E.M.F., especially considering the high current density allowed in the armature.

The following dimensions relate to the type of machine which is now in use at the Cadogan central station :—

E.M.F.	500	volts.
Current	70	amperes.
Speed	800	revolutions per minute.
Ampere turns on field	39,000	
Ampere turns per sq. inch	450	
Total length of magnetic circuit	85	inches.
Section of field-magnets	87	,,
,, iron in armature.	84	
Weight of copper in armature	115	
Watts per lb. of armature copper	305	
Current density in armature	3,750	amperes per square inch.
Length of armature coil	14	inches.
Diameter ,, ,,	18½	,,
Peripheral velocity	3,900	feet per minute.
Number of turns per commutator bar	7	
Number of commutator bars	80	

Air gap 345 sq. in. surface by ·57in. distance from polar surface to armature core.

* See *Electrician*, July 20th, page 334.

Digitized by Google

The machines are separately excited, and are regulated by hand to give constant current.

The above numbers will be found to give an induction of about 14·4 Kapp lines per square inch in the armature core.

LETTERS FOR LEARNERS AND UN-PROFESSIONAL READERS.

BY H. D. WILKINSON.

CHAPTER IX.—*Magnetic Fields.*

(Continued from page 368.)

121. *Polar and Normal Lines of a Magnet.*—In a similar manner the magnetic intensity at points in the field lying in other directions may be found by the application of the parallelogram of forces and geometrical principles; but the two directions in which we have investigated the strength of field are those in which measurements of the magnet and its field are taken, and, therefore, are enough for our purpose.

For conciseness we shall hereafter designate these two directions the *polar line* and the *normal line* of a magnet. The *polar line* will be understood to mean a straight line of indefinite length passing through the two poles of a given magnet, while the *normal line* will mean a straight line of indefinite length at right angles to the polar line, and which also bisects the distance between the two poles. In Fig. 84

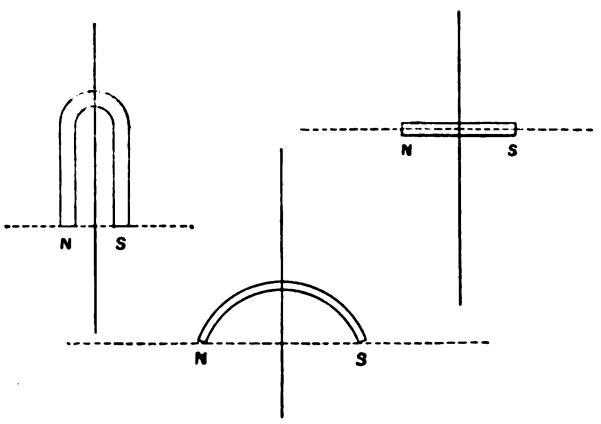


FIG. 84.

three common forms of magnets are shown, their polar lines being dotted, and normal lines shown plain.

122. *The Magnetometer.*—We have already seen (para. 119) that when two magnetic fields of intensities f and H are superposed at right angles to one another at a given point, the ratio $\frac{f}{H}$ is equal to the tangent of the angle between the direction of the field H and the resultant field—that is, the tangent of the angle moved through by a short magnetic needle from its position of rest in the field H. To measure this ratio, then, we require a suspended magnetic needle moving over a scale of degrees by which its movement may be observed. The conditions which are required in such an instrument are

1. Short, well-magnetised steel needle.
2. Long light pointer or mirror attached to same.
3. Long unspun silk fibre to suspend needle and pointer (the length being required to eliminate error due to stiffness or rigidity of fibre).
4. Glass covering over needle and suspension to avoid disturbance by currents of air.
5. Scale divided into natural tangent divisions.
6. Means of accurately levelling.

An instrument for the above purpose is known as a 'magnetometer," and the student will find it an excellent introduction to the theory and use of galvanometers to construct a magnetometer of the simple design here described, and carry out some measurements of magnetic fields with its aid. The following will be found quite simple to make:—A glass funnel, F, of thin glass (Fig. 85) stands inverted on a flat wooden baseboard, B, which should be provided with levelling screws; or a glass flask, with its lower half neatly cut off, answers the same purpose. Through the cork in the neck at the top is pierced a piece of No. 12 copper wire, bent into a ring at its upper end, so that it may be turned round with the finger and thumb, the lower end being filed flat, and a small hole

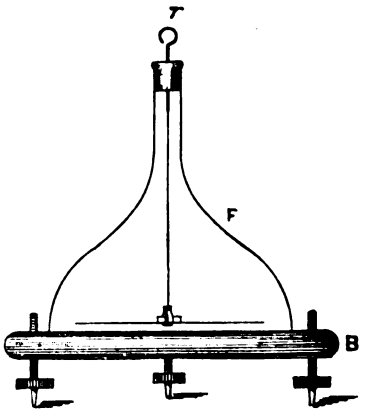

FIG. 85.

FIG. 86

drilled, to which the silk suspension may be tied (Fig. 86). This piece of wire should fit tight in the cork, so that when it is once adjusted it will not slip. The lower end of the silk is then tied to the stirrup. To make the latter stiff note paper does very well, cut to the shape in Fig. 87, the ends being

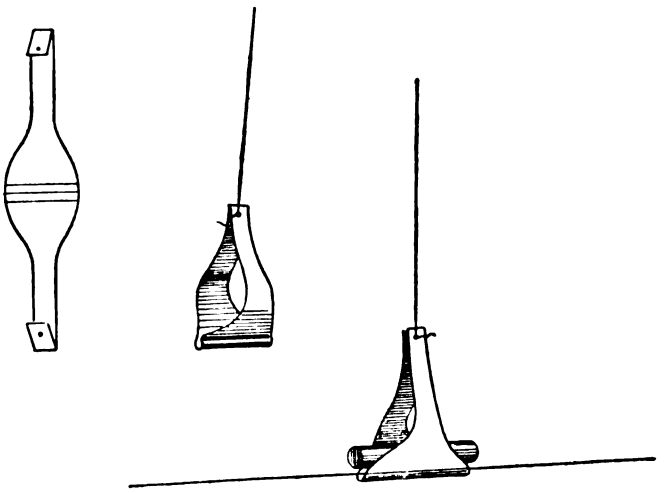

FIG. 87.

folded over as shown to make it stronger, where holes are pierced to which to tie the silk. The three lines across the centre indicate where it should be folded to form a narrow groove at the lower part of the stirrup in which to place the long pointer. This ensures the pointer being in the same line as the needle. The diagram also shows the needle and pointer as mounted in the stirrup. A more durable stirrup may be made in the same way with copper or lead foil. Before mounting the needle and pointer a brass or copper rod about 6in. long should be inserted in the stirrup, balanced, and left for some time till it comes to rest. During this operation the inverted funnel may be lifted off its stand and placed with its edges resting on two supports, so that the hands may conveniently reach underneath to the lower end of the fibre. This process will remove all twist

Digitized by Google

from the fibre. Now the top of the fibre should be turned by turning the ring *r* until the length of the brass rod lies in the magnetic meridian, ascertained by its direction coinciding as nearly as possible with that of a compass needle placed close to the instrument. The brass rod may now be removed by the right hand, while the stirrup is held in the left to prevent it turning, and then the long pointer placed in the lower groove and balanced, and the short magnetic needle placed above it.

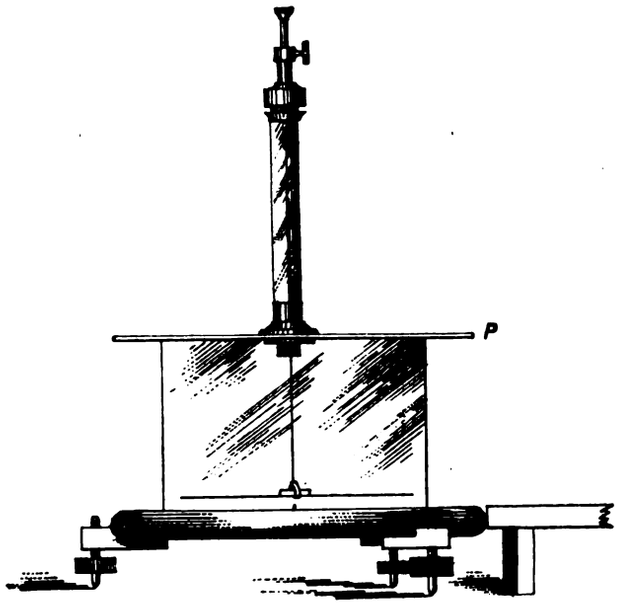

FIG. 88.

The magnetic needle should be about a centimetre long, but not more than 1½ centimetres, and of knitting-needle steel. It requires a little practice to draw out a good, straight, light pointer.

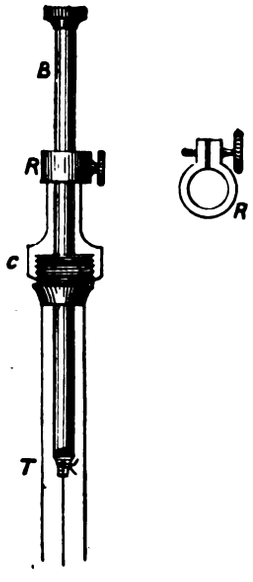

FIG. 89.

Some *thin* glass tubing, about $\frac{3}{16}$in. bore, should be procured, and a piece held by its ends over a Bunsen burner or spirit lamp flame with the two hands, turning it round to heat it evenly in one place till about three-quarters of an inch of it is perfectly red hot, and evenly hot all round. Then removing it from the flame the two ends are pulled, at first quickly, and then slowly, which draws out a fine capillary tube two or three feet long. After pulling out, the fine tube must be kept stretched tight till cool, for if the pull at the ends is relaxed immediately after pulling out, the tube will not cool perfectly straight. The straightest and lightest portion of the drawn tube must now be snipped off to the required length—say, five or six inches, and is then ready for use.

A more elaborate instrument fitted as a magnetometer is shown in Fig. 88, in which the suspension can be controlled with more certainty. The details of the suspension head are represented in Fig. 89, where a tubular brass cap, C, screw-threaded, is cemented on to the upper end of the glass tube T. Above this is a brass tube screwing on at its lower end to the cap C, and carrying at its upper end a split ring, R, through which passes the brass rod B supporting the suspension. The latter may therefore be turned round, raised or lowered as required, and then clamped fast by the screw on the split ring R. The glass tube at its lower end has also a tubular brass cap cemented to it and screw-threaded, a nut on the underside of the circular glass plate P clamping it to the same. A table about 2ft. long and the same height as the baseboard of the instrument will be required for placing magnets on whose fields are to be measured.

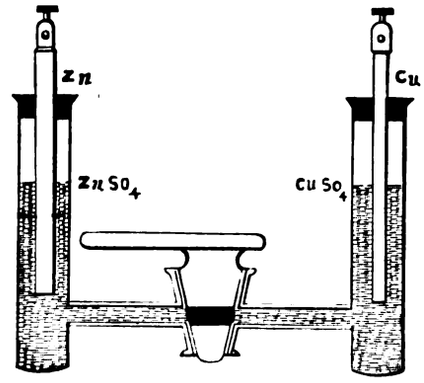
A graduated scale must now be made, by which the movement of the pointer, when the needle is deflected, may be observed. If this is marked out in degrees, the *angular* deflection of the needle will be observed, and the corresponding tangent of the angle must be ascertained from a table of tangents. It is better, however, to graduate the scale in divisions proportional to the natural tangents, the methods of doing which will now be given.

(To be continued.)

ON A CONSTANT DANIELL CELL, FOR USE AS A STANDARD OF ELECTROMOTIVE FORCE.*

BY COSMO I. BURTON, B.SC., F.C.S.

This cell consists of two tubes about three inches long and half an inch in diameter, sealed at one end, and connected together near the closed end by a glass tube about four inches long, having a glass tap in the middle.



The hole through the plug of the tap is filled with plaster of Paris, made as nearly as possible flush with the glass surfaces. This plaster plug serves as a porous septum between the two tubes, which represent respectively the two compartments of a Daniell cell—the one tube containing a copper rod immersed in a saturated solution of copper sulphate, the other a zinc rod in a solution of zinc sulphate, of as nearly as may be the same density as the copper solution. The cell is designed for use only with the quadrant electrometer, and must never be short-circuited.

When the cell is used the tap is turned "on," *i.e*, so that the ends of the plaster plug are opposite the two tubes containing solutions. Immediately that the observations are completed, the tap is turned off, and so diffusion of the solutions completely prevented. The tap is made of the peculiar shape shown in the diagram, in order that it may only be turned in one direction, and so the possible transfer of a minute quantity of the one solution into the opposite tube is avoided.

* From the *Proceedings* of the Royal Society of Edinburgh.

Digitized by Google

Several years ago Mr. A. P. Laurie and I used this cell constantly for four months, and during that time it showed no change of E.M.F., as compared with a standard Latimer Clark, readings being made to three figures only. More recently Prof. Ayrton, of the City and Guilds Technical Schools, London, very kindly undertook to compare this cell with a standard Latimer Clark of his own construction, and also with Fleming's standard Daniell. The results of the comparison are given in the following table. E.M.F. of standard Latimer Clark is taken as unity.

On looking at the cell again, about eight months later, the copper wire was found corroded through, and contact broken. In order to avoid this accident, it is well to use copper rod not less than one-eighth of an inch thick, as copper is somewhat soluble in solution of sulphate of copper. (*See* Gray, *Phil. Mag.*, 1886, p. 389.)

Date.	Standard Fleming, E.M.F.	Experimental Cell, E.M.F.	Temperature of	
			Room.	Standard Latimer Clark.
1886.	0·7466	0·7476	18°·2 C.	16°·9 C.
May 13	0·7462	0·7476		
,, 20	0·7505	0·7485	18°·6	16°·1
	0·7500	0·7489	19°·6	18°·1
,, 31	...	0·7509	17°·9	16°·8
Oct. 7	0·7456	0·7468	...	16°·8

The corks used to support the copper and zinc rods should be carefully paraffined, and every precaution taken to prevent evaporation of the solutions.

The observation in the above table dated May 31 was taken rather hurriedly, and Prof. Ayrton considers it untrustworthy. Omitting this result, it is seen that the experimental cell has a very constant E.M.F., and that the change after about five months was very small.

THE REGULATION OF ARC LAMPS.*

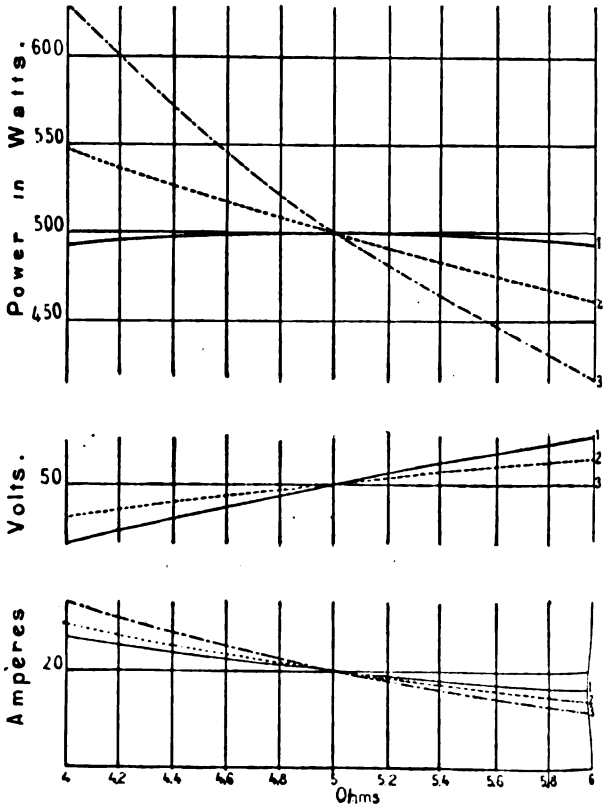
BY M. HOSPITALIER.

It is a matter of common knowledge that arc lamps run off constant potential mains regulate better the greater the difference of potential in the branch; and it is therefore customary to introduce a resistance in series with each lamp. Up to the present time it has, in fact, been impossible to get a steady arc if only that difference of potential is available which is strictly necessary to work the lamps; thus, if 50 volts is the absolute minimum, a tolerably good arc is obtained with 60 volts, and a very good one with 70 volts. Pushing this principle to the extreme, we obtain a perfectly steady arc with a difference of potential of 100 volts, the excess E.M.F. being absorbed by a suitable resistance. The employment of 100 volts with a 5-ohm resistance in series is a method which has been practised with considerable success in exhibition lighting, and it is not to be disdained where steadiness of arc is an absolute essential, as, for instance, in scientific investigations. The part played by this resistance has been misunderstood by some practical men, and consequently we have the erroneous notion that Bunsen cells are *better* suited for arc lighting than secondary batteries. The fact is simply that the internal resistance of a Bunsen battery is equivalent to the resistance which has to be added to the circuit where a secondary battery is used. It is easy to see what part is played by this "electric fly-wheel" by having recourse to diagrams. Suppose it is a question of maintaining an arc under the following conditions:—

Intensity of current C = 10 amperes.
E.M.F. at terminals E = 50 volts.
Power P = 500 watts.

And let us then study the variations of these three factors, when the apparent resistance of the arc, which is normally 5 ohms, varies from 4 to 6 ohms. The consideration of larger variations would not be of much practical use, since even smaller variations than these are quite sufficient to deprive the arc of any pretension to steadiness. In the above diagrams the curves numbered respectively 1, 2, 3 refer to three different sets of conditions. In curve 1 we have a generator giving a constant E.M.F. of 100 volts, the total resistance in circuit, exclusive of the lamp, being 5 ohms. In curve 2 we have a 70-volt generator, the external resistance, exclusive of the lamp, being 20 ohms. In curve 3 we have a 50-volt generator, having a negligible resistance (as in the case of a battery of accumulators) and with no resistance in circuit except the lamp.

On comparing the curves, representing respectively the values of E, C, and P, it is easy to see that with 100 volts at one's disposal all the conditions necessary to good regulation are present; while the exact contrary is the case with 50 volts. What these curves show very plainly is that the power supplied to the arc in case 1 remains sensibly constant as the resistance of the arc varies from 4 to 6 ohms; while if only the strictly necessary 50 volts are available the power supplied to the arc diminishes very rapidly as the arc lengthens, which is the exact reverse of what ought to be, since the arc should absorb more power as it lengthens, in order to compensate for the resultant cooling. These diagrams also show



that a regulator keeping E × C constant is not required in case 1, while it is of great use in case 3. Now the electromagnets which are usually employed only regulate for values of c, but the action of an electro-dynamometer is proportional to C^2; hence, if we could use an electro-dynamometer in lieu of an electro-magnet, we should increase the sensibility of the arrangement and should be able to work satisfactorily, if not with 50, at least with 60 volts, instead of the 70 volts usually employed in cases of mixed distribution. It certainly seems rather wasteful to produce 70 volts at the dynamo terminals and then to use only 50 volts at the most in the arc. The loss thus caused, representing 40 per cent. of the available power, can be reduced by the above device to 20 per cent. The economic advantages of the arrangement are obvious, and we have thought it worth while to call the attention of inventors to this special point of interest.

* From *L'Electricien*.

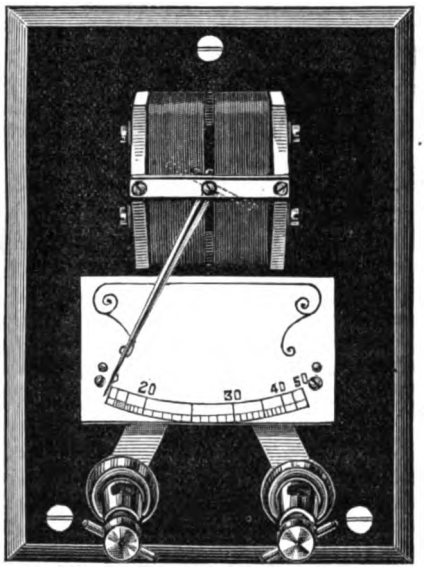
HUBERT DAVIES' ASTATIC AMMETERS AND VOLTMETERS.

We illustrate below a new form of ammeter that has lately been brought out by the United Electrical Engineering Company (Limited), London, and is the invention of Mr. Hubert Davies.

The chief advantages of ammeters and voltmeters of this type are constancy, non-disturbance by outside influences, and simplicity of construction. The conductor through which the current to be measured passes is wound in two coils, one on each side of the pivot which carries the needle system; but, contrary to the usual practice, these coils are so wound that the current passes round them in opposite directions. The pivot carries a system of two or three small soft iron wire needles, which is capable of turning in

Digitized by Google

the space along the axis of the coils, and the motion of the needle system is indicated by a pointer attached near the front end of the pivot, which moves over a scale suitably divided. When the instrument is placed vertically on a switch-board or other support, the needle system is kept in a position slightly displaced angularly from the division between the two coils by the action of a suitably-disposed weight on the pivot, and the pointer then lies at the zero of the scale; but if a current is passed through the coils the soft iron needles become magnetically saturated with poles of the same sign at the two ends and a pole of opposite sign at the middle, and the system turns with its pivot, bringing the ends of the needles more into their coils, and their axis more nearly parallel to the magnetic axis of the coils. The amount of this motion is indicated by the pointer on the scale, as in other direct-reading instruments. The fact of the needle system being magnetised so as to have equal poles of like sign at its two ends prevents the instrument from being affected by outside magnetic influences; so much so, indeed, that it may be used quite close to a working dynamo without sensible error in the indications, and this is an advantage possessed by few other instruments. This magnetic arrangement of the needles is similar to that of an astatic galvanometer, except that the needles are practically placed end to end, instead of one above another; hence the name given to the instrument. In ammeters the coils are generally formed of copper strip, except in the very low reading instruments. For currents of 250 amperes and upwards the conductor is a copper casting of very solid construction, and ample section for the current to be carried. The design thus admits of ammeters of very high as well as ordinary ranges being made, and this applies to the voltmeter also.



Hubert Davies' New Form of Ammeter.

The instruments are mounted on enamelled slate bases, with glass-fronted covers, and appear to be reliably made, and particularly suited for switch-board and similar uses.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *July 28th*, 1888.

Telegraphic matters have been occupying considerable attention during the past week. The settlement of the cable war has been generally received with satisfaction, and, in fact, is looked upon as the beginning of a new era. At first a story got afloat, originating on the Pacific Coast, to the effect that Mr. Mackay had disposed of his Commercial cables to Mr. Gould for $11,000,000, and the report found a great many believers. It was, however, very flatly contradicted. The remarkable thing is that so far from Mr. Gould showing any disposition to buy telegraph properties, he is now said, on good authority, to be quite willing to sell them. The whole situation may be said to hinge, viewed from an outside standpoint, on the state of Mr. Gould's health. About this some most remarkable stories have lately been published. Mr. Gould has not been well for some time past, but the newspapers have credited him with all manner of sicknesses; some have even gone so far as to say that his mind has weakened under the load of business worry. One of the Sunday newspapers presented its readers recently with a most graphic account of Mr. Gould's sitting, lonely and disconsolate, among his flowers, and gazing vacantly at his pet orchids. Under such circumstances, he is said to be willing to release himself from some of his burdens, one of them being the Western Union Company. Stories by no means wanting in weight are afloat to the effect that Mr. Gould is willing and preparing to transfer his telegraphic interests to a very strong syndicate, including two or three rich banking houses, and some of the largest moneyed interests in the country. Of course, the plan may not be carried through, but events appear to be shaping themselves for its consummation. As usual, it will be seen, everything depends upon Mr. Gould, who has been known to do the contrary of what it was said he would do.

While this sensation is steadily working its way to the front, and will soon be occupying no small space in the papers, the United States Senate has passed a Bill which gives evidence of the popular temper with regard to the telegraph service. This Bill relates to the use of telegraph lines along railroads, which have received help from the country generally in the shape of land subsidies. Several of these roads have made exclusive contracts with the Western Union Company. The Bill provides that such contracts shall be at once cancelled. The railroad companies are to operate their lines themselves, and are to make equal rates to all competing telegraph companies without any discrimination. It is rather interesting to note that this movement was begun by the Baltimore and Ohio Company when in opposition to the Western Union Company, and that it now has its results after those two concerns have become one. The practical effect of the Bill is to place the telegraph system of all roads subsidised by the Government under the jurisdiction of the Inter-State Commerce Commission, and thus, for the first time, subjects our telegraphs to direct national interference and supervision.

The agitation for giving the Government a monopoly of the telegraph is little heard of at present; but now and then we get signs of its existence. One of the latest movements in this direction is that fostered by Senator Blair, who has secured for Mr. D. H. Craig, of this city, the use of one of the gallery corridors in the Senate wing of the Capitol at Washington, for the exhibition of certain inventions in rapid telegraphy. Mr. Craig, who will be known, probably, to some of your readers as one of the fathers of our associated press, has for a long time been interested in rapid telegraph schemes, and, so far as I can make out, the object of having this exhibition in Washington within the very walls of the national Capitol is to get the Government to buy the Craig system, and use it in its postal telegraphs. In obtaining the privilege for his *protégé*, Senator Blair informed his senatorial brethren that messages now costing from 25 cents to a dollar could be sent by the Craig system for from 15 to 30 cents, and that 2,000 words could be transmitted by it in the time now required for 400 words. I do not think that the Government will buy Mr. Craig's invention.

Mr. P. B. Delany, of synchronous multiplex fame, has just secured patents on a very interesting and promising system of electrical news bulletins. The arrangement is based on a simple visual telegraph system, which displays its bulletin on a board devised for the purpose, and which makes no record, being, in this respect, the very opposite of the ticker system, where a man has to tangle himself up in miles of tape to find out whether anything has happened that interests him. In the Delany electrical bulletin system, as now arranged, there are 25 type wheels, set all of a row in each board, each wheel carrying the entire alphabet. With 25-letter wheels any item of news likely to interest the public can be given in sufficient detail to make it thoroughly intelligible. Only about a minute is required to complete the spelling out of the bulletin despatch on the board, and then the message can be at once "wiped out," so as to make room for another, or it can stay on the board till such time as the

Digitized by Google

central office has something ready to send and take its place. Of course, if a permanent record is wanted it can be had by transferring the message to a slate below the board, as is generally done here now in connection with sporting news. Every time a new bulletin appears on the board attention is called to it by a bell, and the type is large enough to allow at least 500 people in the room to read it. Such a device has many good features, and the electrical mechanism connected with it is so simple as to ensure the perfect operation of the instruments, of which as many as thirty or forty can be placed on a single circuit, all displaying bulletins simultaneously from a single transmitter. A bulletin of this kind will be a decided acquisition in all places of public resort, such as exchanges, club houses, restaurants, saloons, banking offices, and the like, and I believe that before many months are out we shall see a large number of Mr. Delany's bulletin boards in operation.

The consolidation of the phonograph and graphophone interest has now been formally announced. The price which has been paid to Mr. Edison for his phonograph is said to be half a million dollars, in four payments, and it is understood that this is about as good a return as Mr. Edison has ever had from any of his inventions, not excepting those connected with the electric light. All Mr. Edison's improvements on the phonograph during the next fifteen years are to go into the same hands, and Mr. Edison is still busily at work upon the machine, having recently effected a number of notable improvements on it. The graphophone people are also at work making their improvements, all of which go to the same company, and arrangements are now being perfected for the manufacture of the machine, of which a great many will soon be in use.

The cause of electric motors for street railways has received wonderful assistance from the address just delivered before the local authorities at Brookline, Mass., by Mr. H. M. Whitney, the president of the West End Street Railway Company of Boston. For some long time past this company has been seriously considering the introduction of the cable system for its road in Boston, where it has one of the largest street railway services in the world. Last year the company carried on a few experiments with the storage battery, but there its interest in the use of electricity seemed to end. Plans were accordingly prepared for a very elaborate cable system to be laid down in Boston. It goes without saying that it was no less expensive than it was elaborate. Meantime, however, electric railways were coming to the front, advancing rapidly in perfection of detail and magnitude of performance, and before they made a decision, Mr. Whitney and his associates felt that they ought to look at the latest examples of electric railroading. They accordingly did so, and visited the roads at Alleghany City, Richmond, Va., and Jamaica, L.I. The last-named road is a comparatively crude affair, but, as Mr. Whitney says: "The power was there. The cars were propelled rapidly over the track, and were under complete control." The whole application gave such promise of speedy development, that even before they went any further, the West End directors called a halt on the cable scheme. When they visited Alleghany City they were once more gratified at seeing improvement in this work, and especially with the application of a section of the Bentley-Knight conduit. The visit to Richmond was not less convincing. "What we found there," said Mr. Whitney, "was perfectly surprising and amazing to all of us. There in the City of Richmond, a city of 90,000 inhabitants, was a road 12 miles long over grades and around curves the like of which do not exist in the whole system of 250 miles of the West End Street Railway Company. It is operated by a system of overhead wires which is positively unobjectionable, the cars ascend grades of 9 per cent. at the rate of 6 miles an hour, and are under the most perfect control, carrying the people with the utmost despatch and satisfaction. It was the outcome of one of the hardest conflicts for victory that were ever fought in the industrial field." The result of all this is that the West End Railway Company are not adopting the cable system, and will resort to the electric system of direct transmission by overhead wires and conduit as something vastly superior, and this is the reason why they have appeared before the Brookline Board, in order to obtain permission to run one of their lines out thither from Boston. Such a change of front cannot but attract universal attention. It will convince the general public that the claims made on behalf of the electric railway are not exaggerated, but that the electric method, even as it stands to-day, commends itself to the approval of sober, shrewd and far-sighted men of business. As soon as the necessary permits have been obtained, Boston will thus furnish another demonstration of what electricity can do in facilitating urban passenger traffic, and in meeting one of the greatest demands of the time.

The American Bell Telephone Company has wiped out another opponent. The last contestant to succumb to the Bell patents is Dr. Cushman, against whose company a perpetual injunction restraining from infringement has just been granted in Chicago. I have mentioned in a previous letter the basis of Dr. Cushman's claims, namely, that in 1851, while experimenting with a lightning arrester, he accidentally discovered the principle of transmitting articulate speech, using the electric current as the medium, and that he constructed an operative telephone. The conclusion of the judge is that, however far Dr. Cushman may have gone with his device, it was certainly nothing better than the crudest of experiments, and that all the attempts made to improve the instrument had been complete failures. Hence the judge dismissed the Cushman plea on the ground that all that had been done must be treated as, at best, only an abandoned experiment. Of course there was talk of appeal, but I hardly think the defendant company will push the matter very far.

At the last meeting of the American Institute of Electrical Engineers, one of the speakers, in the discussion on standard resistances, referred to some alloys of Mr. Edward Weston which possessed some remarkable qualities. Recently two patents have been issued to Mr. Weston on these alloys. According to Mr. Edward Weston, the metal manganese imparts a very high electrical resistance, and, in fact, a higher specific electrical resistance than is observed by the addition of any other material to alloys into which it enters as a constituent; and further, the addition of manganese has another valuable property of rendering the electrical resistance of such alloys nearly, or quite, constant under varying conditions of temperature. The alloy mentioned by Mr. Weston consists of manganese and copper, which is prepared by melting together 70 parts of copper and 30 parts of ferro-manganese. This alloy can be rolled and drawn into wire in the usual way. In addition to this valuable alloy, Mr. Weston has obtained still another which has not less remarkable qualities, in that its resistance is lowered by increase in temperature. This alloy is composed of copper, manganese and ferro-manganese and nickel. It is designed to be used in connection with coils of copper or German silver, so that the combination shall form a compensating arrangement by which the resistance of the helix composed of the two shall remain constant, independent of the heating action of the current. With German silver and copper as one part of the coil, Mr. Weston prefers an alloy containing from 65 to 70 parts of copper, 25 to 30 parts of ferro-manganese, and $2\frac{1}{2}$ to 10 parts of nickel.

NOTES FROM PARIS.

(FROM OUR OWN CORRESPONDENT.)

August 7th, 1888.

Paris has hitherto been very scantily furnished with electric fire alarms; in fact, until quite recently, only the first three arrondissements were provided with this necessary apparatus. At the present moment, however, four more arrondissements are being fitted with fire alarms, and only last week the Municipal Council voted some 400,000fr. for the erection of 480 additional instruments, none of which are to be more than 300 metres apart. It is expected that within a year from now Paris will be thoroughly provided in this respect.

The second central station in Paris, that of the Compagnie Parisienne d'Eclairage Electrique, on the Place Ste. Geneviève, is now completed, and the company only awaits the necessary authorisation from the municipal authorities to get to work on the main

Digitized by Google

cables. The plant comprises three dynamos, made by Messrs. Brown, of Oerlikon, each dynamo being driven direct by a separate engine. The station has a 2,000 light capacity.

At the last meeting of the session the Municipal Council voted funds for the erection of a municipal central lighting station at the Halles Centrales, and postponed to the next meeting, in October, the examination of the demands they have received for fitting up central stations in various parts of Paris from several electrical firms. In constructing this station, the cost of which will amount to £40,000, the authorities have a twofold object in view. One-sixth of the total available power only will be devoted to improving the lighting of the Halles, the balance (700 horse-power) will be used for the purposes of private lighting. The charge for the current is to be 15 centimes per ampere-hour. Tenders will shortly be advertised for—1st, boilers; 2nd, engines; 3rd, dynamos; 4th, electric lighting apparatus; 5th, cables. M. Popp has offered to supply compressed air as the motive power, and the authorities seem inclined to entertain the proposal.

THE BRUSSELS EXHIBITION.

(FROM OUR CORRESPONDENT.)

BRUSSELS, JULY 30TH, 1888.

MM. Mourlon, of Brussels, have given a very successful demonstration of the Van Rysselberghe system at the Brussels Exhibition. They have erected two telephone offices, in each of which there is a complete set of Morse apparatus by the side of the telephone transmitters; the two offices are connected by an overhead wire, and talking can be carried on from either end while the Morse apparatus is at work. As an instance of the extent to which this system is in use it may be mentioned that in Europe alone more than 1,300 miles of telegraph wires are so worked, not to speak of the lines in the United States, Egypt, Mexico, Colombia, China, Japan, Costa Rica, Venezuela, Brazil, Uruguay, and the Argentine Republic. The same firm also exhibit the Dejough microphone, which has been adopted by the Belgian Government, and is actually in use on the Paris-Brussels trunk line, over two hundred miles in length. According to a Report of the Société Belge d'Electriciens, this apparatus possesses the most exceptional qualities for the purpose of the transmission of speech. "An experiment frequently repeated and always most successful will give an idea of the value of the system. The listener at the Paris end of the line was able to repeat word for word the sentences whispered by the speaker at Brussels in such a low tone as to be inaudible two mètres off." The Dejough transmitter is on the multiple carbon contact principle, and needs no regulation. Several models of the instrument are shown adapted to various uses. One of these shows the Dejough transmitter in use with the anti-induction apparatus of Van Rysselberghe. This arrangement is intended for railway work, and meets a want long felt, namely, the installation of a number of telephones upon the same telegraph wire, so as to permit any office to talk to any other office. Another noticeable exhibit is the phonotelegraph of Renard Nothomb. This apparatus transmits telegraphic and telephonic messages under conditions which would be impossible in any other system. The currents induced are such that it is no longer necessary to take into consideration the length or, within limits, the insulation of the line. The wire may be of very small section (·001m. diameter), and may be carried along the damp ground, across small streams, and under roads. This instrument, whose compactness renders it very portable and easy to manage, is worthy the attention of the military authorities, since now, more than ever, field telegraphy and telephony has become of the first importance. MM. Mourlon also show one of the microphonic sounding-boards, such as are in use at the Théâtre de la Monnaie to transmit music telephonically to the Châlet Royal at Ostende and to the Palace at Laerken. It was on this occasion that songs and music were first sent some 80 miles over the lines without in any way disturbing the telegraph service. I must not omit to mention a very neat little electro-therapeutic apparatus of Dr. Laroche's, contained in a box about the size of a writing-desk, and comprising a dead-beat galvanometer capable of measuring currents from one milliampere up to one ampere, a battery and a commutator.

The electric lighting of the Exhibition becomes a bigger affair every day. No less than four fresh installations have been commenced, all of which are to be completed by the middle of August, so that M. Bandsept's responsibilities do not lessen; however, I have no doubt that he will continue to make the electric lighting as successful a feature of the Exhibition as hitherto. The Buffalo Bill show is to be lit by 24 2,000 candle-power Thomson-Houston lamps, of which 12 will be provided with reflectors. This installation was only ordered by the executive committee on the 23rd of July, and will be ready by the 5th August. The work is being carried out under the superintendence of M. Admiralli, chief engineer to the Société Belge Thomson-Houston. Another additional installation will comprise seven 7-ampere Poege lamps, run off a Lahmeyr dynamo, which is driven by a 12 horse-power Fétu gas engine. The large Mackenzie-Ross restaurant is now lit by 137 twenty candle-power incandescents, supplied with current alternately by a set of Khotinsky secondary batteries and a 150 volt 190-ampere Thury dynamo. The Khotinsky system of regulation is so perfect that the whole load may be thrown from one source of electricity upon the other without altering the speed of the dynamo or affecting the steadiness of the light. Finally, the large kitchens attached to the Exhibition have been lit up by a number of arc lamps.

In consequence of a few robberies committed after dark in the Belgian Department, the Commissaire-Général decided to close this portion of the Exhibition at 7 p.m., and the foreign sections having followed suit a large portion of the electrical plant lay idle. The technical staff consequently had to find means to utilise the light which the executive committee had agreed to pay for. Hence fresh re-arrangements of plant. Alone, among all the electric light contractors, the Bouckaert-Schukert Company refused to assent to these necessary alterations. In fact, the company are spending the subsidy granted to them by the authorities in a law suit, demanding damages for the alleged injury done to their business by these re-arrangements. I am informed that the Exhibition authorities will plead their contract and regulations, and will make a strong point of the insufficiency of the light supplied by the Bouckaert-Schukert Company.

CORRESPONDENCE.

THE DELANY AND THE WHEATSTONE-STROH CABLE KEYS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In *The Electrician*, July 13th, Mr. F. Higgins states that my cable key "was anticipated by a similar key for the same purpose which was invented by Sir Charles Wheatstone or Mr. Strob, and successfully tried between London and Amsterdam 20 years ago." Mr. Higgins' brief reference to three different systems makes it difficult to understand the order of their era, while his description of the instrument invented by Sir Charles Wheatstone or Mr. Stroh shows clearly that it was in no respect "similar" to mine, but, on the contrary, about as dissimilar as it could possibly be. It may have been "for the same purpose," as it is quite probable that numerous attempts have been made to accomplish the same results; but if, as Mr. Higgins states, the Wheatstone-Stroh invention was tried "successfully" at that time it is certainly very strange that it was abandoned for what Mr. Higgins himself acknowledges to be an inferior method of operation. I think Mr. Higgins has overlooked the intermediate segments in my key and their function, which still further removes it from similarity to the Wheatstone-Stroh instruments. Recent experiments have shown that notwithstanding the fine results obtained by my key, the polarised transmitter with key combination is much superior, inasmuch as the time of contact, making and spacing, is absolutely equal, regardless of the operator's manipulation.

I would be glad if Mr. Higgins will state where a full description of the instrument he refers to can be found.—Yours, &c., PATRICK B. DELANY.

New York, July 25th, 1888.

[The Wheatstone-Stroh key was illustrated and described in our last issue, August 3rd.—ED. *E.*]

TESTS OF THE DELANY CABLE KEY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to the account of a test made with my cable transmitter in your paper of June 29th, I wish to correct a few errors. The cable over which the unprepared test was made is 840 knots, 13,000 ohms resistance, and 240 microfarads capacity. Ordinarily this cable is worked with 15 cells of Fuller battery, about 30 volts. With my transmitter this battery was divided in the middle, giving about 15 volts on each reversal. The speed obtained was 340 complete reversals,

Digitized by Google

or 680 alternating impulses per minute. The strip shows 14 alternating impulses to the inch, and a perfectly uniform undulation of a thirty-second of an inch. No effort was made to ascertain the limit of speed as, on account of lack of battery facilities, it was not expected that any satisfactory results could be obtained.—Yours, &c., PATRICK B. DELANY.

84, Broad-street, New York, July 26, 1888.

UNIPOLAR INDUCTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reply to Mr. Snowdon's letter I may observe, in the first place, that according to the vortex-whirl theory of magnetic action a displacement of the lines of force must correspond to an actual displacement of the vortex filaments themselves, including whatever it is that is in motion.

In Mr. Snowdon's figure, when one of the magnets begins to rotate, the systems of lines of force must be separately considered for the two magnets; the line N S N′ S′ A N, for example, must be considered as consisting of the two closed lines N S A N and N′ S′ A N′, one of which remains fixed, while the other rotates. At any given moment the portion A N′ of a rotating line will coincide with the portion A S of a fixed line of opposite sign—viz., in which the rotation is in the opposite direction—and they will neutralise each other's effects on any magnetic body in the field; but the fixed galvanometer circuit is cut twice at each revolution by each of the rotating lines. I may point out that it is impossible for a vortex filament to terminate in free space, as appears to be suggested in Mr. Snowdon's letter. In the last example, when the core of an electromagnet is made up of two concentric iron cylinders, one of which rotates while the other is stationary, one set of lines must certainly be supposed to rotate while the other remains stationary.

If Mr. Snowdon wishes to maintain the theory that the lines of force of a revolving magnet remain stationary, I must ask him to answer the objections which I have urged on general considerations against this view, in Article IV., pages 232 and 233, and to give an explanation on his theory of the experiments of Exner and Czermak, described in the fourth paragraph of Article III., page 203. The latter appear to me to be quite conclusive in favour of the theory which I have advocated.

I would propose a further question to the advocates of the stationary theory.

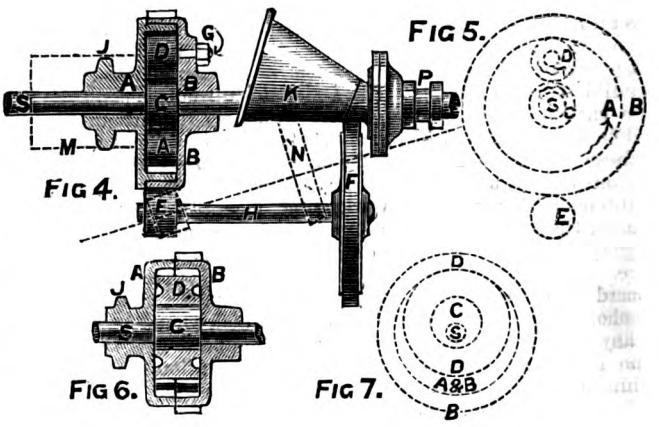
If a magnet can rotate among its own lines of force it will give rise by its own rotation to a difference of electrification of its equatorial and polar portions, so that if these are joined by a wire rigidly attached to the magnet a current will be maintained through the wire and magnet. According to Exner and Czermak's experiments no such current is produced, and I think it can be shown that the existence of such a current would be in contradiction to the admitted principles of dynamics.

Suppose the magnet and rigidly-attached wire to be rotating in space, then the only possible source from which the energy required to maintain the current could be derived would appear to be the energy of rotation of the system. The moment of momentum of the system would therefore be diminished, and ultimately reduced to zero, by its own internal action, which is in direct conflict with fundamental dynamical principles.—Yours, &c., G. W. DE TUNZELMANN.

THE BEAUMONT EPICYCONOIDAL GEAR.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I overlooked the letter in your impression of the 27th ult., in which Mr. Arnall explains what he conceives to be an objection to the epicyconoidal gear described in your impression of the 29th of June. With the velocity ratio and relative diameter of wheels which he has taken for example there would be the high-speed rotation at which he arrives. This has, however, been anticipated, and, as shown in your impression of the 10th September, 1886, the epicycloidal gear is replaced by epicyclic gear, combined with the ex-axial cone when a lower velocity ratio is required. Neither of these forms of gear are original with me, my invention being confined to the combination with such gears of the ex-axial cone, in such a manner as to give to the controlling wheel a variable rate of rotation. In the accompanying engravings, reproduced from your impression of the 10th Sept., 1886, a very common form of internal gearing is shown. The wheel A (Figs. 4 and 5) alone has internal teeth, and is loose upon the shaft S. A pinion, C, is fixed to the shaft, and drives the wheel A by means of the pinion D, which runs upon a stud spindle, G, fixed in the wheel B. The latter wheel is provided with external teeth, with which is geared the pinion E fixed on the spindle H, upon which the friction wheel F is also fixed. When the gear is applied to a tramcar the wheel A runs at its maximum and normal speed when the wheel B is held fast by the pinion E and brake which holds the wheel F, the cone K not being in contact. When it is desired to reduce the speed of the wheel A, with its chain wheel, J, the speed of the shaft S remaining constant, the brake is removed from the wheel F, by a lever which at the same time moves the cone into contact with the periphery of F. The pressure upon the fulcrum spindle G then causes the wheel B to revolve in the same direction as the wheel A, and at a speed which is proportional to the diameter of the part of the cone in contact with the wheel F. The velocity of the wheel A is thus reduced by the velocity of wheel B. When the wheel B is allowed to rotate at the maximum velocity which would be given to A were B fixed, A would receive no motion at all. Fig. 5 shows the directions of movement of the several wheels. Figs. 6 and 7 show one form of the epicycloidal gear not now under consideration, but of the kind shown in the larger engraving in your impression of the 29th ult., and referred to by Mr. Arnall.



With the epicyclic gear, shown in Figs. 4 and 5, any velocity ratio, as between the shaft S and the wheel A, from about 2·5 to 1 to 5 to 1, may be practically obtained, and such gear is very largely in use at high and at low velocities, transmitting small and large powers. It is in use in highly-finished machinery and in roughly finished and roughly handled agricultural machinery, and no difficulty is experienced with it, either with respect to lubrication or to wear. With a tramcar axle running at 100 revolutions per minute this form of gear easily lends itself to the use of a motor running at from 800 to 1,200 revolutions per minute, the normal velocity ratio being from about 3 to about 4·5 respectively, as the chain wheel J would never be made as large as the wheel on the driving axle. The shaft S may be a continuation of the motor shaft, or, where there is not room for the apparatus in this position, S may be a second motion shaft—a better arrangement for numerous reasons.—Yours, &c., W. WORBY BEAUMONT.

Norwood-road, Herne Hill, 7th August, 1888.

RRITISH ELECTRIC COMPANY, LIMITED (IN LIQUIDATION).

A meeting of the creditors of this Company (convened by the official liquidator) was held at the Inns of Court Hotel, Holborn, London, W.C., yesterday (Thursday), to consider the desirability of resuscitating the concern. We are unable to give a report of the proceedings, as reporters were not admitted to the meeting. The official liquidator's report says:—

It has recently transpired that there are good grounds for believing that the interest of the Company under two licenses—one from the Edison Electric Light Company (Limited), and one from the Manchester and District Edison Electric Light Company (Limited), is now of considerable value, and that the licenses may be operated with at a profit, and that it will be beneficial to the creditors of the Company, both secured and unsecured, as well as to the shareholders, that an arrangement should be made between the Company and its creditors, both secured and unsecured, for the satisfaction of the Company's debts with a view to the resuscitation of the Company as a going concern for the purpose of working under these licenses.

For the purpose of carrying out the two objects above mentioned, namely, (1) the satisfaction of the Company's debts, and (2) the resuscitation of the Company as a going concern, a scheme has been prepared, an outline of which is as follows:—(A) The existing debenture holders are to surrender their debentures and abandon their claim for past interest upon receiving new debentures of the Company for amounts equal to the balance of principal moneys due in respect of and secured by the existing debentures held by them, which new debentures will become payable at the expiration of five years after the date of issue, and in the meantime carry interest at the rate of 5 per cent. per annum, and are a first charge by way of floating security upon all the properties and assets of the Company; (B) the other (unsecured) creditors of the Company are to receive fully paid-up Preference shares of the Company carrying interest at the rate of 10 per cent. per annum for amounts equal to 50 per cent. (or one half) of the debts and claims of such creditors against the Company in full satisfaction and discharge of such debts or claims; (C) the Company is to be at liberty to borrow further moneys by issuing debentures; (D) the winding-up proceedings, and also the proceedings taken on behalf of the debenture holders, are to be stayed; (E) Directors are to be elected, and the Company is to proceed to carry on business. A full copy of the proposed scheme may be seen at the offices of Messrs. Clarke, Woodcock and Ryland, No. 11, Lincoln's Inn-fields, London, W.C., solicitors to the official liquidator, on any day between the hours of 10 in the forenoon and 5 in the afternoon, or a full copy will be sent by post upon receipt of a postal order for 5s.

In anticipation of such scheme being carried through, certain provisional agreements have been entered into on behalf of the Company, which it is expected will produce considerable pecuniary returns to the Company.

Mr. Justice North, the Judge to whom the winding up of the Company is attached, has, in pursuance of the powers given him by the Joint Stock Companies Arrangement Act, 1870, directed separate meetings to be held of the debenture holders and of the other creditors of the Company, for the purpose of submitting to them the above-mentioned scheme, and of procuring the passing of such resolutions as may be necessary to give effect thereto.

The following resolution was to be put to the meeting:—

"*1. That this meeting approves of the scheme of arrangement between the British Electric Light Company (Limited) and its creditors, and for the resuscitation of that Company, which has been produced and read and explained to this meeting by Mr. A. A. James, the Chairman hereof, and hereby on behalf of all the creditors (other than debenture holders) of the said Company, agrees to accept fully paid-up Preference Shares in the Company, carrying interest at 10 per cent. per annum, for amounts equal to 50 per cent. or one-half of the respective debts or claims of such creditors against the Company in full satisfaction and discharge of such debts and claims respectively. And hereby further agrees that all the creditors (other than debenture holders) of the Company shall in all respects be bound by the provisions of the said scheme of arrangement, and hereby desires that the said scheme shall be sanctioned by the Court, and rendered binding upon all the creditors of the Company.*"

LEGAL INTELLIGENCE.

EDISON AND SWAN v. HOLLAND AND OTHERS.

In the Chancery Division of the High Court of Justice, yesterday, before Mr. Justice Kay,

Mr. BREMNER, on behalf of the plaintiffs, applied for an order to vary the minutes of the judgment. The registrar had inserted in the minutes an order for an injunction restraining the defendants from further infringing the Cheesborough patent, but, as the defendants' solicitor did not consent, he had refused to insert any order for an inquiry as to damages or for the delivery up of the lamps.

Mr. JUSTICE KAY: Was that asked for at the time?

Mr. BREMNER: It was not mentioned to your lordship at the time, because I assumed that it followed your lordship's judgment in favour of the plaintiff on this point. If I was wrong in making that assumption, I respectfully ask to be allowed to set the matter right.

Mr. JUSTICE KAY: This is asking me to make a different decree; the time for doing that was when I delivered judgment. Does anyone appear for the defendants.

Mr. GRAHAM said the defendants objected to going into an inquiry as to the lamps.

Mr. JUSTICE KAY: If they insist upon it as to that part of the case on which you failed they are entitled to all relief.

Mr. GRAHAM: They are entitled either to an inquiry as to damages or to account to the Court in the alternative.

Mr. JUSTICE KAY: And they elect to take damages. Where the defendants fail on one part of the case, it is not right that the plaintiff should not have all the relief on the other part if he insists upon it. Therefore there must be an inquiry as to the damages, and delivery over of the lamps that infringe that patent.

Mr. GRAHAM then referred to the order as to costs. In connection with the Cheesborough process, they were to be taken as between solicitor and client; but were they to be taken on the higher or the lower scale?

Mr. JUSTICE KAY: Why should I give part of the costs on the higher scale and the rest on a different scale? I understood the higher scale was certainly to apply to all the costs in the action.

Darcy v. The Liverpool Electric Supply Company.

At the sitting of the Chancery Court for the County Palatine of Lancaster, held at St. George's Hall, on Wednesday, before Vice-Chancellor Bristowe, judgment was given in the action Darcy *v.* the Liverpool Electric Supply Company (Limited).

This was an action for an injunction to restrain the defendants, their servants and workmen from working certain steam engines and electrical machines in such a way as to cause a nuisance or injury to the plaintiff and his premises, No. 11, Highfield-street, Liverpool. The plaintiff was, and is, lessee and occupier of the premises mentioned, which consist of a fully-licensed public-house, held for the residue of a term of fourteen years from the 1st December, 1886, created by a deed dated 11th January, 1887, made between John D. Fox on the one part and the plaintiff on the other part. In answer to the claim, the defendants said by an agrement with the plaintiff's landlord (Mr. Fox) the company had leave and license to do that which was now complained of.

The VICE-CHANCELLOR, in giving judgment, said that he came to the conclusion that this was so, but if he should be wrong in this view—after having heard the evidence, and having personally visited the premises—he was of opinion that the evidence of the plaintiff had been greatly exaggerated. He could hear no noise, and he could detect no vibration which could in any way be prejudicial to the comfort and enjoyment of the premises. He therefore dismissed the plaintiff's claim with costs.

PATENT RECORD.

RECENT APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

10,524. B. J. B. MILLS. London. Improvements in electric railways (the Bentley-Knight Electric Railway Co., United States). July 20, 1888.

10,568. F. H. ROYCE. Manchester. Improvements in the manufacture of electric bells. July 21, 1888.

CRICKET.

Eastern Telegraph Company v. Enfield.

This annual match was played at Bush Hill Park, on Monday, the 6th inst., and resulted in a win for Enfield. Mr. M'Millan's bowling was remarkable; in the first innings he took eight wickets for five runs, and in the second five wickets for eight runs. Mr. Gardner also bowled well in the second innings, taking five wickets for 11 runs. Mr. Capel played a dashing innings, and Mr. Collyer batted with great care. Mr. Hibberdine was captain of the Enfield team and Mr. A. O. Penney of the Eastern. Scores:—

Eastern Telegraph Company.—*First innings:* A. O. Penney, b Capel, 0; F. W. Penney, b Dodd, 1; E. Gardner, l b w, b Capel, 2; T. Richardson, run out, 1; W. Kerwin, b Capel, 1; J. Belbin, b Dodd, 0; G. Penney, b Dodd, 0; W. J. M. D. Wells, l b w, b Dodd, 0; J. Beavis, run out, 0; E. Blake, run out, 0; W. Brace, not out, 0; W. Chisholm (absent); J. M'Millan (absent); extras, 5—Total, 10. *Second innings:* A. O. Penney, c M'Lennan, b Wells, 22; F. W. Penney, run out, 0; E. Gardner, c Dodd, b Stewart, 3; T. Richardson, c Steward, b C. S. Collyer, 2; W. Kerwin, b Steward, 0; J. Belbin, b Steward, 1; G. Penney, c Caney, b Steward, 0; W. J. M. D. Wells, b M'Lennan, 0; J. Beavis, not out, 1; E. Blake, b Wells, 1; W. Brace, b M'Lennan, 15; W. Chisholm, b Dodd, 1; J. M'Millan, c C. S. Collyer, b Dodd, 2; extras, 4—Total, 52.

Enfield.—*First Innings:* J. M. Capel, c and b A. O. Penney, 76; W. Wells, b Gardner, 3; C. S. Collyer, c and b M'Millan, 55; C. Dodd, c Kerwin, b M'Millan, 8; J. A. Caney, b M'Millan, 7; A. T. Penney, b M'Millan, 0; P. O. Woollard, b M'Millan, 0; T. Steward, c and b Chisholm, 1; G. A. Collyer, b M'Millan, 4; G. H. M'Lennan, c Beavis, b Gardner, 0; W. Hibberdine, c and b Gardner, 3; W. S. Smith, not out, 0; extras, 7—Total, 164. *Second Innings:* J. M. Capel (absent), 0; W. Wells, b M'Millan, 8; C. S. Collyer, b M'Millan, 0; C. Dodd, c M'Millan, b Gardner, 0; J. A. Caney, b M'Millan, 3; A. T. Penney, b M'Millan, 5; P. O. Woollard, c Richardson, b Gardner, 1; T. Steward, b Gardner, 1; G. A. Collyer, b. Gardner, 0; G. H. M'Lennan, c and b M'Millan, 1; W. Hibberdine, not out, 0; W. S. Smith, b. Gardner, 0—Total, 19.

CHELTENHAM—REPORT OF THE LIGHTING COMMITTEE OF THE TOWN COUNCIL.

At the meeting of the Cheltenham Town Council, held on Tuesday last, the committee appointed some six months ago to report upon the advisability of lighting the town by electricity brought up the following report:—

"That in the opinion of the committee it is desirable to try the experiment of lighting a portion of the town with the electric light. That the area to be lighted be as shown on the plan now laid before the committee by the surveyor. It is considered that 36 lamps, each of 1,200 candle-power, will be sufficient to efficiently light this area, and that about 170 gas lamps will be thereby rendered unnecessary. Assuming that the lamps can be supplied, either by the Corporation itself or by contract at the price of the tender accepted by the Bath Corporation for 70 similar lamps for a term of seven years, viz., £18. 17s. 6d. per lamp, exclusive of the standards, the annual cost to the Corporation, exclusive of the standards or brackets, would be £679. 10s.; from this would have to be deducted the cost of the gas lamps superseded, which at the present cost per lamp of £2. 13s. 6d. would amount to £454. 15s. per annum. That it be referred to the Committee to consider and report as to the best mode of carrying out the foregoing recommenda-

Digitized by Google

tion, whether by the Corporation itself or by contract, and if the former alternative is considered preferable, to report as to the best means of carrying the works into effect; if the latter to procure tenders."

Mr. GEO. NORMAN, Chairman of the Electric Lighting Committee, said that if they passed the report that day a more elaborate statement would be brought up at some future meeting—probably next month—and it would then be in the power of the Corporation to commend or reject it, as they pleased. Subject to this, the present minutes, he admitted, were of an important character. They asked the Council to say that the electric lighting of the streets was desirable, if a proper scheme were submitted; to approve of the experimental area which the surveyor had sketched out; and also to give the committee the freedom referred to in the concluding sentence, namely, to consider, whether, supposing the light was adopted, it could best be carried out by a private company, or by the Corporation themselves. Taking the second of these points first, as being the least important, he might say that the experimental area shown on the plans included the principal streets of the town, and it touched, he believed, every ward in the town. But the committee cared little about this matter of detail, and they were prepared, he believed, to curtail or extend the area, as the Town Council or applicants might think fit. Before passing from that part of the subject, it would be well to state that the figures given in the minutes were rather an illustration of the committee's proposal than a part of it. For instance, to be quite fair, there should be added to the cost of the electric light the cost of maintaining the posts upon which the lamps were placed. This, however, was a small matter; at Taunton the lamp posts and fittings cost only £3 each, and the interest on that expenditure was certainly slight. It should be further explained that the committee had taken their estimate upon the contract accepted by Bath, which was for a larger number of lights than that proposed in the present scheme; but they had done so because they anticipated that the number reached in Bath would also be reached in Cheltenham. It was difficult to realise that it was now some six or seven months ago since the committee was appointed, and perhaps it might be thought that they should have taken some earlier occasion to report. But the delay had not been a disadvantage to the subject of electric lighting, for during the time that had elapsed the committee had been able to make several interesting visits—namely, to Taunton and Eastbourne, which were both very successfully lighted, and also to electrical works in London, and the time thus spent had been useful to the committee, in that it had removed any doubt that members might have entertained, and enabled them to bring up their report with the weight of a unanimous body. That was something to be gained, and he hoped that before the question was done with it would be the unanimous resolve of the Town Council that the new, but now well-tried, illuminant should be publicly utilised in Cheltenham. There was, moreover, the further advantage which had sprung from delay, that the public had been familiarised with the subject; they had had it brought home to them, and many of them had been afforded opportunities of seeing what a beautiful light that of electricity was, and how superior to gas. The speaker then referred at considerable length to the progress of the electric light in London, Edinburgh, Dublin, Birmingham, Bradford, Southampton, Ilfracombe, Leamington, Bath, and other places. There was one highly important direction in which he hoped Cheltenham would see its way to improve upon the course taken by Bath. He was quite sure that if it could be effected at anything like a similar cost, or at anything like a reasonable cost, it was far better to have underground wires than overground wires, and even more strongly did he hold that this work should be in the hands of the Corporation. That was a question which would come before them at a future time, when the Council would be in a better position to discuss it; but if the Corporation decided to take up this question he should not in the least fear to ask the ratepayers to put up with a loss, perhaps a considerable loss, upon the early lighting of the town by electricity. It was fair to remind them that when the gas company started the gas company had to put up with a loss, and what Corporation would not go through a similar experience to possess such a noble property as the gas undertaking in Cheltenham now was? He wished he felt strong enough at the Council to initiate some practical measure, and he should be glad to follow anyone who led in that direction, for he was bold enough to think that the gasworks, equally with the supply of the electric light, ought to be in the hands of the town. If the Council gave the authority which the Electric Lighting Committee asked of them to-day, he hoped that when they next reported they would show by the data which they would then have collected that they had paid due attention to the subject, and that they were fully sensible of the weight of the responsibility which the Corporation had placed upon their shoulders (applause).

Mr. WAGHORNE seconded.

The resolution was then put to the meeting and carried unanimously.

COMPANIES' MEETINGS.

The Cuba Submarine Telegraph Company (Limited).

The thirty-fourth ordinary general meeting of this Company was held on Wednesday last, at the offices of the Company, 61, Old Broad-street, E.C., under the presidency of Joaquin de Mancha, Esq., chairman of the Company.

Mr. JAMES SCOTT (the secretary) read the notice calling the meeting, and the report of the Directors was taken as read.

The CHAIRMAN: Well, gentlemen, it is again my pleasing duty to meet you with a very favourable report, and in consequence there is very little to be said. I think it speaks for itself. You will find that the increase is going on very favourably. We have about 10 per cent. increase in the number of messages, and the income has also increased in the same proportion. The expenses are very much the same as before, and you will see, although we have repaired our cable, under the direction of our manager abroad (Mr. Keith), we are still able to show a very good result. The only extra charge that we have had has been what we have paid to the Spanish Government for the use of their land line whilst our cable was in course of being repaired. The cost has been very insignificant, only £180, and it did our business very satisfactorily for us. The accounts show that we have made, together with the amount brought forward, £24,274. After paying all expenses, which have amounted to £6,879, there is left a balance of £17,395 for us to dispose of. That will enable us to pay the usual dividend of 10 per cent. on the Preference shares, and we will propose that that be paid and also a dividend at the rate of 9 per cent. on the Ordinary shares. I think that, taking everything into account, we cannot be other than satisfied with such a result, and only hope it will continue for some time to come. Our cables are all in good working order, but as our old cable has been now laid for so many years, it may require one of these days to be thoroughly overhauled. That will entail, of course, a certain expense, which makes us the more careful to make our reserve fund as strong as possible. I am sure it is to the advantage of the Company that our reserve fund should be strong, so that in the event of any emergency we may be prepared to meet it without diminishing our dividend (hear, hear). If there is any gentleman who wishes to have any further explanation I shall be very glad to give it him. As regards this year, for the last month's traffic, I am glad to tell you that there is still an increase, and we have had 570 messages more than we had at the same time last year (cheers). I have much pleasure now, gentlemen, in moving that the report and accounts as presented for the half-year ended 30th June, be received and adopted (cheers).

Mr. ALEXANDER F. LOW: I beg to second that.

Mr. WILLIAMS: There is one question that I should like to ask, and that is that I see that our reserve fund, or the greater part of it, is deposited in various banks; I should like to know at what rate of interest. I am a shareholder in the Eastern and Eastern Extension Companies, and we invest our reserve fund in debenture stocks. I am merely asking for information. I do not wish in any way to reflect upon the Board.

The CHAIRMAN: Well, sir, the reason is that debenture stocks do not pay so much. We have been getting 5 per cent. from most of the banks. Times, however, are not so favourable now for money, and the interest has been reduced in some cases.

Mr. WILLIAMS: I see that by London banks a very small rate of interest is paid.

The CHAIRMAN: We are getting 4, 4½, and in one or two cases 5 per cent. I will give the names of any of the banks if you would like to know.

Mr. WILLIAMS: No, no.

The CHAIRMAN: I assure you we take the greatest care in selecting the banks. We have diminished some of the amounts. The sole reason is we get a little more than we should from debenture stocks.

Mr. WILLIAMS: You think, then, it is a better plan than to invest money in debenture stocks, as other companies have done?

The CHAIRMAN: I am connected with one or two other companies, and we find the policy of leaving our money in the hands of our bankers a satisfactory one. We only do it for a year or two, and can always call it out whenever we want it.

Mr. WILLIAMS: I would like to ask one other question. Have you any idea of doubling our cable at all, as I see when anything happens to our one cable we are "hung up"?

The CHAIRMAN: I mentioned that one of these days it might be desirable to entirely overhaul and make thoroughly in good condition our Batabano cable, not to double it entirely, and therefore we wish to be strong and ready in case such a course should arise.

Mr. WILLIAMS: Quite so.

The motion was then put and carried.

The CHAIRMAN then moved—

"*That the following dividends for the half year be now declared upon the shares of the Company, viz., at the rate of 10 per cent. per annum, subject to income-tax, on the Preference shares, and 9 per cent. per annum, free of income-tax, on the Ordinary shares, payable on and after to-morrow.*"

Mr. LOW seconded the motion, which was carried.

The CHAIRMAN then said that his next duty was to propose the re-election of Mr. Horatio J. Perry as a Director of the Company. It was usual for one to retire by rotation each year. Mr. Perry had been connected with the Company since its formation, and his colleagues found him very useful. He resided abroad, in case they wanted anything done at Madrid. He looked after things efficiently. He begged to formally move—

"*That Mr. Horatio J. Perry be re-elected a Director of the Company.*"

Mr. WILLIAMS seconded the motion, which was carried.

The CHAIRMAN said that the next motion was for the re-election of an auditor, and it properly came from the other side of the table. He could assure the shareholders that they possessed in Mr. Greenwood a thoroughly efficient auditor, and he did not think that they could do better than re-elect him. No one could look after the accounts more carefully than he did.

Mr. WILLIAMS said he should be very glad to propose—

"*That Mr. Thomas Greenwood be re-elected Auditor of the Company for the current year at a salary of twenty guineas.*"

Mr. SQUIRE begged leave to second Mr. Greenwood's nomination.

The motion was carried.

Mr. THOS. GREENWOOD: Gentlemen, I thank you very much for re-electing me to the office of auditor, and I shall do my duty as before.

Digitized by Google

The CHAIRMAN said that concluded the business.

Mr. SQUIRE said that before they separated he thought that they should thank the Chairman and Directors for the manner in which they had conducted the affairs of the Company during the past six months, and he specially endorsed their principle of increasing the rest by the substantial amount they had done (hear, hear). He quite agreed with the Chairman that that was their sheet anchor, and it was better to forego a small present increase of dividend rather than put that amount in peril (hear, hear). He begged to move that they return thanks to the Chairman and Board of Directors for their good management and exceedingly good report that they had been able to present to the shareholders.

Mr. GREENWOOD wished to be allowed to second that. He should be very glad to do so. He had had the pleasure before of speaking as to the satisfactory manner in which the business was conducted. The accounts were exceedingly sound, and the dividend extremely good.

The motion was carried.

The CHAIRMAN said that on behalf of himself and colleagues he wished to thank the shareholders for their kind vote. He trusted that he would be allowed to include in it the name of their worthy secretary (Mr. Scott), who was almost daily at his (the Chairman's) office, consulting him respecting the interests of the Company. He would like also to include the name of Mr. Keith, who was present that day, on leave of absence. Mr. Keith was most valuable to them. If any repairs were found to be required he started off at once and conducted the operations in a most efficient way. He had saved the Company, he (the Chairman) was going to say, thousands of pounds, but, at any rate, a great deal of money. Mr. Keith was a Scotchman, and they were usually ready men; but Mr. Keith seemed to be more than usually ready. He would move, with the approval of the meeting, a vote of thanks to Mr. Keith, their worthy secretary, and the rest of the staff, for the efficient way they had carried out the Company's affairs.

Mr. SQUIRE: Perhaps I ought to have included them in the vote of thanks to the Chairman and the Board.

The CHAIRMAN said he was glad to have the opportunity of moving the resolution himself, as the Directors saw more of the staff and their work than the shareholders did. They liked to bestow merit were merit was due (cheers).

Mr. GREENWOOD was pleased to second the resolution and to give his testimony as to the manner in which the affairs of the Company were conducted. A considerable amount of care was taken by their Secretary in the conduct of their business. He (the speaker) had not seen Mr. Keith before, but he had often seen his signature, and read his letters. Mr. Keith seemed to anticipate everything that required to be done.

The motion was unanimously carried.

Mr. KEITH said he had to thank them for the very flattering way in which his services had been referred to. He begged to thank them very much on his own behalf and that of the staff. They always tried to do their duty.

Mr. J. SCOTT: I thank you, gentlemen, on my own behalf for your kind vote.

The meeting then separated.

National Telephone Company (Limited).

The eighth annual ordinary general meeting of this Company took place on the 4th inst., at the offices, Queen Victoria-street, under the presidency of Colonel R. Raynsford Jackson.

The SECRETARY (Mr. Wm. B. Campbell) read the notice convening the meeting; and the report of the Directors was taken as read.

The CHAIRMAN then said: The report, gentlemen, speaks very much for itself, and the remarks I shall make to you will be mainly with the view of bringing more prominently to your notice some of its salient features. The first point to which I shall call your attention is that the revenue which the Company had reached on the 30th of June amounted to £109,572. 12s. 7d. and that this was an increase upon the revenue reached at the same period in the previous year of £17,235. 10s. 3d. Of that increase of revenue a certain proportion, namely, £1,200, is due to fee messages. If you look at the abstract, you will see that we have somewhat altered the first divisions. Last year we did not distinguish between annual rentals and fee messages, and we headed that column with "gross revenue." I believe the heading "gross revenue" was somewhat misleading. Some thought it was the gross revenue realized for that year. We have altered the heading, in order to prevent the possibility of similar mistakes. It is the annual gross income arrived at on the 30th of June last. Then I will ask your attention to the heading "trunk wires." The length of pole lines is now 842 miles, or an increase of 199 miles during the year. The length of wires carried by these poles is 2,509 miles, or an increase of 590 miles on the length of the previous year. Then, under the heading of "new exchanges," you will find that we have increased the number of exchanges by 26, and the number of lines by 1,470; and if you look at the second page of the report you will see a minute statement showing the number of subscribers in our various centres, and that the total number of lines is now 9,324. I ask you to examine this a little carefully. The towns bracketed together are in communication with each other by trunk wires, and it may be interesting to you to know that before the middle of next month we anticipate to have the trunk line completed between Sheffield and Birmingham, which will put Nottingham, Derby, and the Birmingham district into communication with Yorkshire and the Lancashire and Cheshire system. When we meet again I hope also to have the Potteries district connected with Birmingham as well as with the Lancashire and Cheshire system, giving communication with Manchester in almost a straight line from Birmingham, which will enable us, when the Birmirgham and London line is completed, to have direct telephonic communication between London and Manchester. I will ask you next to look to the item "debenture" stock in the capital account. We have converted our debenture bonds (at all events, to the extent of £70,700 out of £75,000) into debenture stock. £60,900 of the debenture bonds were at 6 per cent., and £14,100 at 5 per cent, and the debenture stock has been placed at 4½ per cent., thus diminishing the charge upon the company for interest. This is all I shall say upon the progress of the company, but I wish to point out that that progress would have been quite impossible but for the change made by the late Mr. Fawcett in the powers granted to the company on November 29, 1884, and I will ask you to cast your eyes at the map on the wall. It is different from the other maps in this respect—you see that the outline in red represents the boundary of the National Company's districts, and that the little red spots show the small parts of the whole area that we were allowed to give the telephone to under our old licenses. Take for example the Yorkshire district. We were allowed to exploit towns with small contiguous areas—say four miles around Bradford, five around Leeds and a smaller area around the other towns—and we were not allowed to connect these towns with each other. Even when the districts overlapped we were not permitted to run trunk wires from town to town, as so much desired by the community, as giving a larger range to telephonic conversation. The fact is that these little spots represent the oases in a great waste which alone were allowed to have the benefit of the telephone. Mr. Fawcett, a large-minded and liberal statesman, saw that the restrictions upon the use of the telephone which then existed were not for the advantage of the community, and granted us licenses which have enabled us to enlarge the system to the extent I have described, and to connect nearly all our centres with each other, giving altogether a telephonic system which has the merit of being extensive and effective, and of supplying almost all the telephonic wants that are as yet developed. Had we remained under the old licenses telephonic enterprise in this country would have been a disgrace to a nation which professes to be in the van of commercial progress. I ask your attention now to the subject of amalgamation. I have nothing to add to what was said by the chairman of the United Telephone Company upon that subject. I think he put the position of the companies towards each other on that question very fairly before his shareholders. There is one point he dwelt upon and recurred to a second time about which I want to say a few words. I will give you his exact observations. He said, "It would be idle, however, to shut our eyes to the fact that questions may arise on which different opinions may legitimately be held, and of course may be more or less difficult to solve. The question as to the value to be attached to undeveloped business is an apt illustration of what I mean." Upon that point I will merely observe this, that as far as we are concerned we shall have to guard ourselves against the possibility of having to pay dividends upon capital awarded to other companies, on account of what may be supposed to be their prospects, out of the actual earnings of this Company. I do not apprehend that we shall find the difficulty insuperable. My own experience is that where people approach each other in a fair state of mind, with a desire to accomplish a given object, not dealing with each other in a grasping spirit, but on the principle of give and take, difficulties in negotiation are generally overcome, and I cannot see why our case should be an exception to that rule. That is all I think it necessary to say to you to-day, excepting this: that our relations with the Post Office are, as hitherto, most amicable. It is perhaps desirable to repeat that fact, because when we have so much to do in various ways with a great public department our shareholders may necessarily wish to know how we stand with that department. I shall be prepared to answer any question that may be put to me, and now I will propose—

"*That the report and accounts for the year ended the 30th June, 1888, be received and adopted.*"

Colonel HARRISON briefly expressed his pleasure in seconding the motion.

The CHAIRMAN: If no questions are to be asked I will put the resolution. Having put the motion in the usual manner, he declared it carried unanimously. Continuing, he said: The next resolution is—

"*That a dividend at the rate of 6 per cent. per annum, less income-tax, be paid upon the First Preference stock for the six months ended 30th June, 1888.*"

Mr. SAMUEL H. SANDS seconded the motion, which was carried unanimously.

The CHAIRMAN: I now move—

"*That a dividend at the rate of 6 per cent. per annum, less income-tax, be paid upon the amount paid up on the Second Preference stock for the six months ended 30th June, 1888.*"

Mr. S. D. WILLIAMS seconded the resolution, which was carried unanimously.

The CHAIRMAN: I have now to move—

"*That a dividend at the rate of 5 per cent. per annum, free of income-tax, be paid on the Ordinary stock.*"

Mr. T. A. DICKSON, M.P.: I have great pleasure in seconding the resolution just proposed, and I think it is only right to say that in getting a dividend of 5 per cent. now on the Ordinary stock, I regard such a distribution as a very remarkable fact in connection with the development of this telephone company. I remember five or six years ago, when I first became connected with the Telephone Company, that I had little idea of seeing 5 per cent. paid upon the Ordinary shares of the company, but under the able management of Colonel Jackson—who is deserving of all praise from the shareholders of the Company, and whose whole thoughts night and day are, I believe, connected with our interests—we have reached the position of getting 5 per cent. upon the Ordinary shares. I think such results as we have obtained are entirely due to the able management of our Chairman. I have great pleasure in seconding the motion.

Digitized by Google

The CHAIRMAN put it, and it was carried unanimously. He afterwards proposed the re-election as a member of the Board of Mr. John Bruce, observing that that gentleman was a very active, able, and useful Director of the Company.

Colonel HARRISON seconded the motion, and it was carried unanimously.

The CHAIRMAN next proposed the re-election as a Director of Mr. Jeremiah Garnett, whom he described as an active and energetic member of the Board.

Mr. SANDS seconded the resolution, which was carried unanimously.

On the motion of Mr. DICKSON, M.P., seconded by Mr. JOHN LEAKE, Messrs. Quilter, Welton, and Co., were reappointed auditors to the Company.

Mr. DICKSON: Before we separate I think it is only right that we should accord a vote of thanks to Colonel Jackson, our Chairman, and to the Directors for the manner in which they have conducted the business of the Company during the past six months. I have already referred to the services of Col. Jackson in pioneering this Telephone Company so successfully upon its path hitherto. I believe that telephone enterprise is only yet in its infancy in this country. We are far behind America and many other countries, and I look forward to the time—not many years hence—when our revenue shall be 50 per cent. more than to-day (hear, hear). I have no hesitation in saying that our prosperity and position to-day in this Company are mainly, or entirely, owing to the unwearying zeal given to our interests by our Chairman and his colleagues on the Board. I have very great pleasure in proposing that the best thanks of this meeting be given to Col. Jackson and the Directors, and I think I should couple with their names the name of our secretary, Mr. Campbell. I have known Mr. Campbell for some years as secretary of this Company, and I can only say, from my personal knowledge of him, that he is worthy of a vote of thanks. I have great pleasure in proposing this vote to those gentlemen.

Mr. JOHN LEAKE seconded the motion, and it was carried unanimously.

The CHAIRMAN: Gentlemen, I thank you for the vote of thanks which has been so kindly proposed by Mr. Dickson and accepted by the meeting. I wish to say that it gives me infinite pleasure to see a larger assemblage of our shareholders to-day than we have ever had before. Generally the number of shareholders attending our meetings is much more limited. Now I am glad to see that the shareholders are beginning to take more interest in our progress, and I hope in another year we shall have a still larger muster if the National Telephone Company continues at that time to have a separate existence. I thank you for myself and colleagues.

The SECRETARY also acknowledged the vote, and the proceeding then terminated.

NEW COMPANIES REGISTERED.

MONTEVIDEO TELEPHONE COMPANY (LIMITED).—This company was registered on the 31st ult., with a capital of £180,000, in shares of £5 each, to carry on the business of a telephone company in all branches. The first subscribers are:—

	Shares.
F. A. Christie, 4, Albion-villas, Stoke Newington, London, N, clerk	1
J. B. Munro, 35, Linton-street, London, N., clerk	1
H. C. H. Gibbs, 2, Abbeville-road, South Clapham, clerk	1
R. Matthew, 54, Wharton-road, West Kensington-road, W., clerk	1
G. Jackson, 34, Gloucester road, Holloway, N.	1
D. R. Crane, 3, Earlam-road, Cliftonville, S.E., shorthand writer.	1
H. B. Clifton, 2, Shanklin-road, Crouch End, N.	1

The number of directors is not to be less than three, nor more than seven; and the first are to be elected by the subscribers; qualification, the sum of £250 in stock or shares of the company; the remuneration of the directors is to be the sum of £150 per annum each, with a further sum of £50 to the chairman.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended August 3rd, 1888, amounted to £5,601.

CHELSEA ELECTRICITY SUPPLY COMPANY.—Letters of allotment in this company have been posted.

CUBA SUBMARINE TELEGRAPH COMPANY.—The number of messages passing over the lines of this company during the month of July was 3,850, estimated to produce £3,100, against 3,280 messages, producing £2,607, in the corresponding month of last year. The traffic receipts for the month of April, estimated at £3,700, realised £3,705.

DIRECT SPANISH TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the month of July, 1888, amounted to £1,518, against £1,538 in the corresponding period of last year.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY.—The traffic receipts of this company for the month of July, 1888, amounted to £35,233, and to £38,520 in the corresponding period of 1887.

EASTERN TELEGRAPH COMPANY.—The traffic receipts of this company for the month of July, 1888, amounted to £48,735, and to £45,805 in the corresponding period of 1887.

GREAT NORTHERN TELEGRAPH COMPANY.—Traffic returns: Receipts in July, 1888, £24,000; 1st January to 31st July, 1888, £156,000; corresponding months, 1887, £150,520; ditto, 1886, £147,560.

METROPOLITAN ELECTRIC SUPPLY COMPANY.—Letters of allotment and regret in this company have been sent out. We understand that the applications were largely in excess of the amount of the issue.

MONTE VIDEO TELEPHONE COMPANY.—The English Bank of the River Plate invite subscriptions for £180,000 of share capital, divided in 24,000 six per cent preference and 12,000 ordinary shares of £5 each, of the Monte Video Telephone Company (Limited), which has been formed to acquire as a going concern the concession, rights, patent privileges, plant, exchanges, and other property belonging to the telephone company known as La Sociedad Anonima Compania, Telefonica La Uruguaya, in the city of Monte Video. The Uruguay Company was incorporated in the month of April, 1885. It commenced operations with about 450 subscribers; since which it has made rapid progress, and by the latest information received from Monte Video, the total number of telephones now working are 1,610. A telegram from Monte Video states that the net receipts for the first four months of the Uruguay Company's current year, ending 30th June last were $18,800, or at the rate of $56,400 per annum, equivalent to £12,000.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended August 2nd, 1888, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company, were £4,673.

WEST COAST OF AMERICA TELEGRAPH COMPANY.—The traffic receipts of this company for the month ended July 31st, 1888, amounted to £4,550.

PATENT
SILICIUM BRONZE AND SILICIUM COPPER WIRE.

The Right Hon. LORD SUDELEY, P.C., F.R.S.
LEOPOLD SALOMONS, Esq.
JOHN C. SALT, Esq.
C. A. WHITMORE, Esq., M.P.

Offices—WINCHESTER HOUSE, OLD BROAD STREET, LONDON, E.C.

The principal objects of the Corporation are:—

1. Performing the duties of Trustee, Executor and Administrator.
2. The Insurance of Bonds, Shares and all other Securities lodged with the Corporation against risks of all kinds.
3. The Issue of Warrants and Certificates against Securities deposited, and making and procuring advances on such Warrants.

The Office of Trustee or Executor is to private persons usually a thankless post, involving much anxiety, time and money, and frequently leads to serious actual loss; whilst death, illness and change of residence necessitate frequent fresh appointments, and consequent expense to the parties interested. The Corporation undertakes all the duties of Executor, Trustee or Administrator for reasonable remuneration proportioned to the work and responsibility in each case.

The Corporation insures existing Trustees and Executors against all risks attending those positions, where the business is conducted by the Solicitors to their Trusts under the supervision of the Corporation, it not being the desire of the Corporation to interfere in any way with the duties of the family solicitor.

The Corporation acts as Trustees for the Debenture Holders in Public Companies.

For terms, &c., application should be made to the General Manager at the Company's Office.

GEORGE PEARSON, *General Manager and Secretary.*

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL SCIENCE, INDUSTRY AND ENGINEERING.

No. 535.—Vol. XXI. FRIDAY, AUGUST 17, 1888. Price 4d.

NOTES.

The arrangements for the meeting of the British Association at Bath are rapidly advancing towards completion; and although the meeting will scarcely compare in scientific interest with that of last year, when so many distinguished foreign members were present, yet there is every reason to anticipate a very interesting and pleasant gathering. We have already announced that special arrangements have been made for a discussion on Lightning Conductors, in which Sections A and G will take part. Mr. Preece, in his Presidential Address in Section G (Mechanical Science), will pass under review the various practical applications of electricity, with most of which Mr. Preece has himself been associated from the very first. He will also say something about the theory of electricity which can hardly fail to be of considerable interest. Prof. Forbes will read a Paper on "The Westinghouse System of Electrical Distribution," which he has had exceptional opportunities of studying. In the absence of Mr. Cowles, Mr. Crompton will read a Paper on the Cowles process for the reduction of aluminium; and about half-a-dozen other electrical Papers have so far been arranged for in this section.

In Section A (Mathematics and Physics) Prof. Fitzgerald has accepted the Presidency in the place of Prof. Schuster, whose health compelled him to decline the post. From Prof. Schuster, had he been able to occupy the Presidential chair, we should no doubt have heard something of the highest interest and importance on the phenomena of electrical discharges in rarefied gases, or on terrestrial magnetism—questions to which Prof. Schuster has devoted long years of labour. Prof. Fitzgerald, on the other hand, will probably summarise the latest results of mathematical and physical research in the electro-magnetic theory of light, and as this is a subject in which some remarkable experimental advances have quite recently been made, the address will be looked forward to with special interest.

The proposal of the United Telephone Company to establish a local exchange system and call stations, for what may be called "domestic" purposes, in the Kensington district, has, on the whole, been received with favour. The experiment will certainly be watched with interest, as likely to afford conclusive evidence as to whether such popular applications of the telephone service can be made to pay in the metropolis—a point on which, apparently, the company itself has long remained sceptical. The experience of provincial towns and districts justifies a sanguine view of the result; and there is no excuse for the adverse criticism which has already been offered to the scheme on the score of its excessive charges. Telephone extensions are very costly affairs, expenses increase quite disproportionately with increased business, and there is no known method of increasing the capacity of the telephone wire. Those who complain of the charge of 6d. for three minutes' conversation by telephone are perhaps ignorant of what can be earned on a telegraph wire in the same number of minutes—ordinarily ten times, possibly twenty times, as much. Particulars of the Kensington scheme may be found in our advertisement columns.

The following extract from a private letter to the Editor, written by M. Gaston Planté, and which we have obtained his permission to publish, will certainly be read with interest. The reference is to a note which appeared in the same issue (August 3rd) in which we reviewed M. Planté's work on "Atmospheric Electricity." He says:—

"I have read with interest the experiment which you cite, and which was made by Mr. Mordey at the works of the Brush Company. If the arc produced between the carbon electrode and the salt water did not appear to take a globular form, probably the light of the arc was too dazzling, or else the E.M.F. of the current was not sufficiently high. It is better to employ an electrode of platinum or *d'amiante humide* (? moistened asbestos), when the globular heaping up of the *liquid* may be observed in salt water with an E.M.F. of 500 volts. To produce the globular form of the arc above distilled water an E.M.F. of 2,000 volts is necessary. I shall be very glad indeed if those who have machines of high tension at their disposal will repeat my experiments, but every precaution should be taken to avoid the dangers which attend the handling of such high E.M.F.'s. In all cases it is better to employ a shunt circuit, for a large current is not necessary. It is *tension*, not quantity, which we require."

The experiments of Wheatstone, and the fact that rapidly-moving bodies when illuminated by lightning appear as if at rest, have led to the belief that the duration of the lightning flash is almost infinitesimally small. M. Trouvelot has, however, obtained evidence, apparently of an unimpeachable character, which shows that, at least in a particular case, the flash had a duration of several seconds, during which it preserved the same form. Writing in *La Lumière Electrique* he says:—

"Lightning does not possess the instantaneousness generally attributed to it. One of the photographs which I obtained during the storm of the 22nd of last month clearly proves this, showing

Digitized by Google

that this particular flash, at any rate, was by no means instantaneous, but lasted several seconds. At the moment of the flash I gave the photographic apparatus a slight horizontal motion, lasting at least three seconds. Now, this movement is faithfully reproduced in the photograph, the image of the flash being displaced some six millimetres. This being the case, we ought to be able, by means of suitable mechanism, giving the camera a uniform motion, to measure accurately the duration of flashes. The photograph shows that the flash had already lasted some time when the apparatus was moved, and also that it lasted some time after the motion had ceased, the edges of the illuminated belt being more sharply defined than the intervening space. This flash, like all which I have hitherto succeeded in photographing, is ribbon shaped, and is traversed by a number of streaks. The displacement of the camera also shows that the form of the flash did not sensibly alter, for the sinuosities are identical at the two extremes of the photograph, three or four seconds having elapsed."

THE lack of a simple and expeditious means of measuring the strength of the magnetic field has long been felt. LIPPMANN'S method (depending on the alteration in the height of a balanced column of mercury placed in the field to be measured, and through which a current is passed), although remarkably ingenious, is open to serious objection. The employment of glass tubing is of itself almost fatal to its usefulness in practical measurements of dynamo machines. At last, however, it would seem that a method is available which promises to fulfil every reasonable condition, and for which we are inclined to anticipate a considerable field of usefulness. It has long been known that the electrical resistance of bismuth is increased when it is placed in a magnetic field, and LEDUC proposed to employ this property to measure, empirically, the strength of the field. But the increase of resistance observed in ordinary bismuth is not so marked as to render the phenomenon very readily available. Now, however, Drs. LENARD and HOWARD have succeeded in preparing flat spirals of bismuth wire in which the resistance increases from about 10 to about 20 ohms in a field of 17,000 C.-G.-S. units. An ordinary Wheatstone bridge measurement and a table of reference will therefore enable the dynamo manufacturer to measure any field into which a thin flat spiral can be inserted. For full details the reader is referred to an article on another page.

THE important electrical patent litigation between the proprietors of the "Thomson-Houston" and "American" systems of electric lighting has just been decided by the United States Courts in favour of the former, as holding the only fundamental patent on automatic current regulating machines. We understand that this may be expected to be followed by a similar trial of strength between the Thomson-Houston Company and their rivals in this country.

IT is impossible not to sympathise with Admiral FIELD and others—not, perhaps, including Dr. TANNER—in their opposition to, or, rather, in their demand for further time to consider, the Bill empowering LLOYD'S to acquire land and establish electrical communication with lighthouses, lightships and signal stations for life-saving, and maritime signalling purposes. There is, on the face of it, a grave practical objection to conferring on a private corporation powers which ought to be exercised by the Post Office, and which, in time of war, must confessedly be surrendered to one or other Department of the State. Our own criticisms of the Bill would be somewhat different, namely, that it leaves to voluntary action, determined by considerations of profit, a duty which ought to be discharged with more exclusive regard to the safety of the nation and its commerce. As, however, the Government is not prepared to establish a complete system of telegraphic communication round the coast, we may be thankful for even the limited promises held out by LLOYD'S. The House of Commons finally adopted this view, and the Bill was read a third time last Friday night.

WHEN the City and Southwark Subway Company first came into notice we strongly urged that the line was particularly well adapted for working by electricity. Moreover (as is our invariable practice in such cases), we took especial care that our arguments should come under the notice of those for whose immediate benefit they were intended. It has now for some time been practically settled that electric traction is to be adopted, and at the meeting of the company on Tuesday last (which we report more fully in another column), the chairman announced that the line would probably be in working order by this time next year. Although, as we have said, the employment of electric traction is practically settled, the particular system to be selected is still an open question. Both a parallel and a series system have been, and we believe still are, under consideration, but in any case accumulators will not be employed —in fact, they have not even been suggested. It is, perhaps, not too late to add that we are a little sorry that the company, in seeking for technical advice, should have called in the services of a gentleman who, however eminent as an engineer of railway telegraphs, has not hitherto devoted special attention to electric traction. The applications of electricity are now far too wide for any one man, however clever, to cover the whole ground. Submarine Cable Companies do not go for advice to Mr. KAPP or Mr. MORDEY, and even Mr. PREECE is not, we believe, an eminent authority on the subject of electro-metallurgy.

THE applications of electrical science form no exception to the general rule that there are at least two ways of doing things—a right way and a wrong way. But we cannot help thinking that the people who prefer the wrong method of treatment are somewhat excessively numerous where electricity is concerned. There are people, as we all know, who are anxious to work heavy railway traffic with secondary batteries; there are others who prefer incandescent lamps of 16 candle-power for lighting open spaces, and still others who like to see powerful arc lamps in small retail shops. Cases are even on record where alternating currents have been preferred to continuous currents for working direct from the machine, while the devotees of the art and mystery of electric lighting by primary batteries we have ever with us. To this day there are London banks who prefer to communicate with their branch offices by means of the Wheatstone A B C instrument at three words a minute.

But by far the most inexplicable and indeed astounding instance of the kind which has yet come under our notice is to

Digitized by Google

be found in a recently published "interview" in the *Pall Mall Gazette*. Sir EDWARD WATKIN, who on this occasion was the victim, expressed to the reporter a very reasonable surprise that such an enterprising line as the London and North-Western still adhered to the archaic method of signalling from the passenger to the guard by means of a piece of string fastened outside the window. It is not in this instance, however, the string, but the substitute proposed, that fills us with astonishment. Sir EDWARD was able to point with conscious pride to the fact that the South-Eastern—as befits a model railway company—had long ago adopted an electrical method of communication. Yet, ever anxious to perfect any trifling defects which may still be found upon the South-Eastern line, Sir EDWARD "has been trying for some years, to use for this purpose, the telephone" (!)

"What I shall do, I think," Sir EDWARD magnanimously proceeded, "is to offer a little prize of a hundred guineas or so for a solution of the problem of talk between passenger and driver, and talk between passenger and guard. Of course there are many difficulties, vibration and so on, but in my judgment there is nothing that cannot be overcome. If it could be done, that would be a revolution. When an old woman feels she can talk to the guard and her conversation will be registered by the telephone company [here Sir EDWARD becomes a little incoherent]—we should have to carry telephone boys on the engine or in the van—she feels it a comfort; she is no longer, as she fancies, between a certain person and the deep sea. At present, of course, it would not do to stop a train because a man thinks the carriage is shaky when it is perhaps only his nerves. With a telephone he could talk away, and properly explain whatever he wished. That," Sir EDWARD added, "is one of my pet projects, and another is the electric locomotive."

The spectacle of some "poor devil of the public" (as Sir EDWARD WATKIN phrased it in the same interview) trying to communicate with the guard by telephone, while attacked by garotters on the South-Eastern Railway is one which the imagination positively reels to contemplate. We have, however, one hope to buoy us up; we believe that Sir EDWARD made a fatal mistake in introducing that reference to the old woman, and on the day when the one hundred-guinea prize is awarded we confidently anticipate a strike amongst the passenger guards of the South-Eastern. Nevertheless, all this furnishes no excuse for the North-Western and other railways who have neglected to provide electrical communication.

SOME of us have laughed at the schoolboy who, when asked to compose a theme On Pins, wrote "Pins have saved a great many lives by not swallowing them." Perhaps the Pitsville workman who, a little while ago, fell from the roof of a house and was saved from being dashed to pieces by a pair of electric lighting wires would take the story more seriously. It is said that the two leads were carrying a current of 1,000 volts, alternating current, which effectually prevented him leaving go until some one came with a long ladder and helped him down. Thus it would appear that the full force of a powerful current, so far from killing him, actually saved the man's life; but he is probably the first person who has received such a current and been thankful for it.

Cowpen, Northumberland.—The Cowpen District Local Board are inviting tenders for arc and incandescent lighting. Particulars may be found elsewhere in this issue.

Vicenza.—The Municipality of Vicenza has granted a nine years' concession to M. Conti to establish a central station for the purpose of lighting the private houses of the town by electricity.

The Telephone in Burmah.—The *Indian Engineer* says that a rival telephone company in Burmah has obtained sanction from the Local Government to open out a new line in opposition to the Oriental Telephone Company.

Pekin.—It is stated that the Chinese Emperor is expending £1,400 on an installation in his palace grounds at Pekin, and should this prove a success we may expect to see his august example followed by the notabilities of the empire.

Madrid.—The city of Madrid will soon have a large central station of 1,000 horse-power capacity, constructed by a local company called "La Luz Natural." The wires will be run overhead, and the charge is to be five centimes per hour per lamp of 16 candles.

Sale of Electrical Plant by Tender at Bournemouth.—We would call attention to the notice which will be found in our advertisement columns respecting the electrical plant which is offered for sale by the liquidators of the Bournemouth Electric Light and Power Company.

Yacht Lighting with Accumulators.—In addition to the Queen's yacht, "Victoria and Albert," we understand that Messrs. Drake and Gorham have recently fitted a set of accumulators on the Prince of Wales's yacht "Osborne." The cells are found to answer their purpose well, and are naturally felt to be a great convenience.

Belting.—According to experiments recently made at the Royal Polytechnic School at Munich, the strength of camels' hair belting reaches 6,315lb. per square inch, whilst that of ordinary belting ranges between 2,230lb. and 5,260lb. per square inch. The camels' hair belt is said to work smoothly and well, and it is unaffected by acids.

Plumstead District Board.—At the last meeting of this Board it was resolved, on the recommendation of the General Purposes Committee, to inform an electric lighting company who had served Parliamentary notices, that, subject to the rights of the public being protected, they would look favourably upon the introduction of electricity into the district.

Bank of England.—We are glad to hear that in addition to the 500-light installation recently erected, the Bank have now decided to make a further extension, and Messrs. Drake and Gorham have received instructions to put down two additional engines. Two more Elwell-Parker dynamos will be fixed, and two batteries of cells made to Messrs. Drake and Gorham's specification.

Electric Traction.—The American *Street Railway Journal*, which has recently described numerous electrical tramway systems more or less under trial, says:—"That the science of electrical propulsion has reached perfection no man will attempt to maintain, but that it has reached the stage of practical and economical utility every unprejudiced person should freely admit."

SS. "Norham Castle."—The Castle line Royal Mail Steamer "Norham Castle" has lately been fitted throughout with the electric light by the Anglo-American Brush Corporation. The installation comprises two 180-light Victoria dynamos, driven by two independent engines, and 320 16 candle-power incan-

Digitized by Google

descent lamps. The circuits are so arranged that in the event of a partial breakdown the most important parts of the ship can still be lighted. The electric light has further been applied to the side and masthead lights, and also to a submarine lamp, by means of which the ship's hull and propeller can be easily examined by the aid of a water telescope.

Chelsea Vestry.—At the last meeting of the Chelsea Vestry the Electric Lighting Committee submitted a letter from the Chelsea Electricity Supply Company, Draycott-place, Cadogan-street, Chelsea, stating that the whole of the amount required as capital (£32,000) had been provided, and that the company would begin work without delay.—The report of the committee was adopted, on the motion of Mr. C. Mossop.—The Surveyor said he had received from the company a list of the streets on Schedule A in which the company proposed to lay wires without any unnecessary delay. The surveyor added, in answer to a question, that all the wires would be underground.—The assent of the vestry to the intention of the company was given.

The Rates for Press Telegrams.—In the House of Commons, on August 10th, Mr. Cochrane-Baillie asked the Postmaster-General whether, in view of the report of the Committee on the Revenue Departments, he could state that the Government would bring in further legislation to relieve the country from the loss incurred by the present agreement in connection with the sending of press telegrams. Mr. Raikes said, having regard to the fact that the charges for press messages were fixed by statutory power conferred by the Telegraphs Act of 1868, and that the charges levied had been in operation upwards of eighteen years, he feared it would be difficult to make any change. The question of further legislation was, however, one more for the First Lord of the Treasury than himself.

Automatic Gas Lighting.—At the annual meeting of the North British Association of Gas Managers, Mr. G. Keillor, of Nairn, read a Paper on a method of automatic gas lighting which he had successfully carried out. The actual lighter contained nothing novel, the well-known form supplied by the Woodhouse and Rawson Company having been found perfectly efficient. The novelty consisted in the combination with this apparatus of a delicate governor actuated by the pressure in the main, and by which the circuit of the battery is closed or opened whenever the pressure is increased or diminished to the point for which it is set. In this way, by the mere regulation of the pressure at the gasworks, any number of lamps supplied with the electric lighter may be simultaneously lit or extinguished.

Interruption of Cables to the East.—The Eastern Telegraph Company notifies the interruption of its Aden-Bombay cables. The repairing ship will be in the locality of the fault in a few days' time. Until the communication is restored, telegrams for India, China, &c., should be sent through the lines of the Indo-European Telegraph Company.—The Indo-European Telegraph Company announce that one of the cables of the Indian Government, between Bushire and Jask, in the Persian Gulf, broke down on the 13th inst. at noon. The Indian Government have now, therefore, only one working cable by the Indo-European route. The Government repairing steamer "Patrick Stewart" is on her way to the fault, and the repairs are expected to be completed between the 20th and 22nd inst.

Dalkeith.—At a meeting of the Police Commissioners of Dalkeith on Monday last—Provost Gray presiding—Baillie Watson said that as the town was now in possession of a powerful gas engine, he believed it would be beneficial for the community at large if it could be utilised for the purpose of producing electric light as well as pumping water. He believed the engine to be capable of doing both; and then the business premises and dwellings of the townspeople, to the surprise and admiration of all, would be lighted with a light somewhat approaching the light of the sun in purity and splendour; and for this end he proposed that they appoint Messrs. Alison, Liddell, Baillie Murdoch, and himself a committee to make the necessary inquiries with a view to accomplishing so desirable an object. The motion was agreed to, and Bailie Watson was appointed convener.

St. James's Vestry.—At the last meeting of the Vestry of St. James's it was resolved, on the motion of Mr. Keevil, with respect to the Electric Lighting License—(1) That no overhead wires or cables shall be placed within the jurisdiction of this Vestry; and as to clause 14, after the word "street," this clause shall end. (2) That this Vestry will not approve of any concession or license being granted to any electric light company to supply such light to this parish, unless the license provides that after the shareholders of such company have received an annual dividend of ten per cent. one half the surplus shall be set aside and applied towards the funds of this parish, or in diminution of the charge for lighting by electricity the public streets. (3) That all correspondence and matters in reference to granting a concession by this vestry to any electric lighting company shall be submitted to the legal advisers of this vestry to report thereon before being finally confirmed.

The Crystal Palace School of Practical Engineering.—On Saturday, August 11th, the certificates awarded to the students in this school as the result of the examination on the work of the past term were distributed by Mr. A. T. Walmisley, C.E., President of the Society of Engineers. In the electrical section Mr. Sydney Evershed officiated as examiner, and presented the following report:—"I have visited the School during the past session, and also looked over the papers worked by the students at the summer term examination. The electrical section is conducted on an excellent system, by which, in addition to a thorough grounding in the theory of electricity, the students receive practical instruction in the management and working of electrical plant. The inspection and repairs of the machinery used for lighting the Palace and grounds being entrusted (under supervision) to the students, they have exceptional facilities for acquiring most valuable technical skill and experience."

City and Guilds of London Institute.—The Report on the Technological Examinations held in May last connected with this Institute has just been issued, and shows a steady progress in every department of technical instruction. During the past year 10,404 students were under tuition in 475 classes, spread over 183 different towns in the United Kingdom. The corresponding numbers for the previous year were 8,613 students, 365 classes, and 121 towns. These numbers do not include the students at the Finsbury and provincial colleges, the candidates from which are classed as "external." Of the provincial towns, Manchester as usual heads the list with the largest number of candidates passed, Glasgow occupying the second place. Of the 10,404 students at the registered classes, 5,240 came up for examination, and 2,892 of these succeeded in passing. Including the external candidates, trained at colleges or in private, the total number of passes was 3,516, of whom 2,510 passed this year for the first time. We regret to notice that the percentage of failures among candidates in the several branches of electrical engineering has slightly increased.

Electrical Communication with Lighthouses.—Sir Michael Hicks-Beach presided on Thursday, the 9th inst., at a meeting of the House of Commons Select Committee appointed to in-

Digitized by Google

quire into Lloyd's Signal Stations Bill, the object of which is to enable Lloyd's to acquire lands compulsorily when required for the purpose of placing outlying lighthouses and islands in communication with the mainland by electricity. Sir Richard Wyatt, who appeared for the promoters of the Bill, said that it was the outcome of the investigation of a departmental committee who recommended it with a view to saving life at sea. The difficulty had presented itself to Lloyd's of persons trying to obtain an unreasonable price for a bit of land required for the purpose. The committee passed the preamble of the Bill. In the House of Commons on the following day, after a warm discussion, the Bill was read a third time. Exception was taken to it by several members on the Government side of the House because of the little time afforded for considering its provisions; but more especially because the task which the Government itself ought to carry out thoroughly would be very inadequately performed by a private company. Sir Michael Hicks-Beach, however, pointed out that the second clause of the Bill gave to the Postmaster General power to prescribe conditions which would secure the very objects which the critics of the Bill so anxiously desired.

Electric Lighting at the Exeter Asylum.—A report was made to the Exeter Town Council at their last meeting to the effect that the first cost of lighting the local asylum by electricity was £2,160 and the cost per annum £118. Under the contract Messrs. Woodhouse and Rawson were to supply storage batteries capable of maintaining 100 lamps of sixteen candle-power for fourteen hours without running the engine and dynamo. On the completion of the installation Mr. Massey, electrical engineer, reported that the storage batteries would run 100 Woodhouse and Rawson's lamps the specified time, but no other lamps then in use. Subsequently an injunction was granted against the use of Messrs. Woodhouse and Rawson's lamps as being an infringement of the Edison-Swan patent, and upon the lamps being changed it was discovered that the storage batteries would run 100 Edison-Swan lamps for nine hours only. The committee of the Asylum, having called upon the contractors to increase the power of the storage batteries, were met by the reply that they were advised that as the contract was for the erection of specified apparatus to the satisfaction of the architect they were not bound to provide additional storage batteries, those erected having been certified as complete and as having answered the test. They thought it was unfair to ask them to put in new cells, but they were willing to meet the Council to a small extent.

Ilfracombe.—A special meeting of the Ilfracombe Local Board was held on Friday last to consider the question of lighting the promenade. All the members were present with the exception of Captain Dennis and Mr. Lake, and Mr. Darbyshire presided. A letter was received from Mr. Woodley relative to the electric light. He said he could make no reduction from £150 stated, and this he understood from the chairman would only be for eight months out of the twelve. After he received this letter the surveyor said he had wired that the Board would not pay for gas for the engine, and he had received a reply stating that he (Mr. Woodley) would accept for eight months and find gas for £150. The letter received from the Gas Company at the last meeting was again read, by which it appeared that the company would supply gas at 1s. 3d. per hour, and charge £50 for the fittings. The total candle-power would be 2,500. The Surveyor said the electric light was 5,740 candle-power, but it was a question whether this was necessary.—Mr. Russell then moved that the question of lighting the whole town with electricity be considered; that tenders be invited for this purpose.—Mr. Thomas seconded.—Mr. S. Day considered that the tender should be thrown open to the Gas Company as well.—Mr. Thorold was of the same opinion, and it was resolved that tenders be invited both from the Gas Company and the Electric Lighting Companies. It was further resolved that notice be given to the Gas Company to terminate the present contract at Lady Day next. With reference to Mr. Woodley, the Surveyor was instructed to wire to him that the matter of lighting the shelter was still under consideration, and the Clerk was instructed to write to the Gas Company and ask them if they would be willing to fit up the shelter at their own cost with Wenham lights for one month, and supply a special meter, so that the Board could see the quantity of gas consumed and the quality of light produced.

Electric Traction on the City of London and Southwark Subway.—The eighth half-yearly ordinary meeting of the shareholders of this company was held at Winchester House, Old Broad-street, on Tuesday afternoon, Mr. Charles Grey Mott, the chairman of the company, presiding. The report stated that the construction of tunnels, both on the section to the Elephant and Castle and to Stockwell, had made considerable progress, and that the works were being carried on at all the station shafts along the route. Nearly the whole of the land and property required for the railway and stations had been acquired, and the directors were satisfied to record that the total cost will be somewhat less than the original estimate.—The Chairman, in moving the adoption of the report, after referring to the progress which was being made in the construction of the railway, said that the question of the best method of working the line, and the nature of the power to be used, had for some time past occupied the special consideration of the directors. It was essential that whilst the trains should be very frequent, and the transit rapid, the cost of running and maintenance should be kept as low as possible. In many respects the system of endless cable would seem to be the best, but it had certain disadvantages in its application to the working of the line which it was not easy to overcome. After much careful investigation the directors had arrived at the conclusion that electrical force, conveyed by continuous conductors, offered the best solution of the difficulty, and would give a motive power at once reliable and economical. Several firms had made proposals for the working of the line in this way, and negotiations were in progress for a practical trial of the system before a final decision was arrived at. The directors had been assured that the electrical working of the line in an efficient and economical manner did not present any difficulties; and, in fact, offers to undertake the working of the line at a fixed sum per annum had been received; but, as the directors were anxious to obtain the authorisation of the shareholders, a special meeting was to be held later in the day. It was necessary that the matter should be decided promptly, as the engineer hoped to get the work of tunnelling as far as the Elephant and Castle completed by the end of the year.—Mr. Walter Robinson having seconded the adoption of the report, it was unanimously agreed to, and the meeting was then made special in order to consider the question of empowering the directors to adopt electricity or any other motive power except steam, which is precluded by the Act, they might think desirable. Two or three shareholders expressed the opinion that the original idea of an endless cable should be adhered to, as they considered the adoption of electricity of too experimental a character. Eventually, however, the resolution proposed by the Board was adopted, and the proceedings terminated in the usual manner.

THE EFFICIENCY OF THE EXCHANGE TELEGRAPH COMPANY'S HYDRAULIC POWER PLANT WHEN USED FOR CHARGING ACCUMULATORS.

BY F. HIGGINS.

The following description of the hydraulic apparatus employed by the Exchange Telegraph Company in the production of electricity for working over 600 of their telegraphic instruments in the City and East End of London will probably be of interest to the readers of *The Electrician*:—

The apparatus, as will be seen in the accompanying drawings, consists of a Brotherhood engine, a Gramme dynamo-electric machine, and electrical accumulators.

The motor and dynamo with countershafting are mounted upon a timber frame which is quite independent of the building, the whole platform resting loosely upon a thickness of boiler-felt upon a wooden floor. The motor cylinders, three in number, are 4in. in diameter, and the pistons have a stroke of 3in. The fly-wheel is 4ft. 6in. in diameter, and its relatively slow speed of 48 revolutions per minute is augmented by means of gearing to 930 at the dynamo, two belts being employed, the larger being a 5in. double and the smaller 4in. single. The dynamo is shunt-wound, and of the ordinary Gramme type, made by Johnson and Phillips.

The accumulators, 210 in number, are of the Electrical Power Storage Company, or E.P.S. form, in glass cells, mounted upon Johnson and Phillips's oil insulators, and connected in three series of 70 each for charging.

The E.M.F. produced by the dynamo at the before-mentioned speed is 194 volts, and the normal output of current is 15 amperes, the resistances of the various parts of the circuit being—

Armature, 1·256 ohm.
Field-magnets, 123·746 ohms.
One set of accumulators, 1·236 ohm.
The greatest potential observed of one set of the accumulators is 154·46.

From these data, and taking 746 watts to the horse-power, the power absorbed is:—

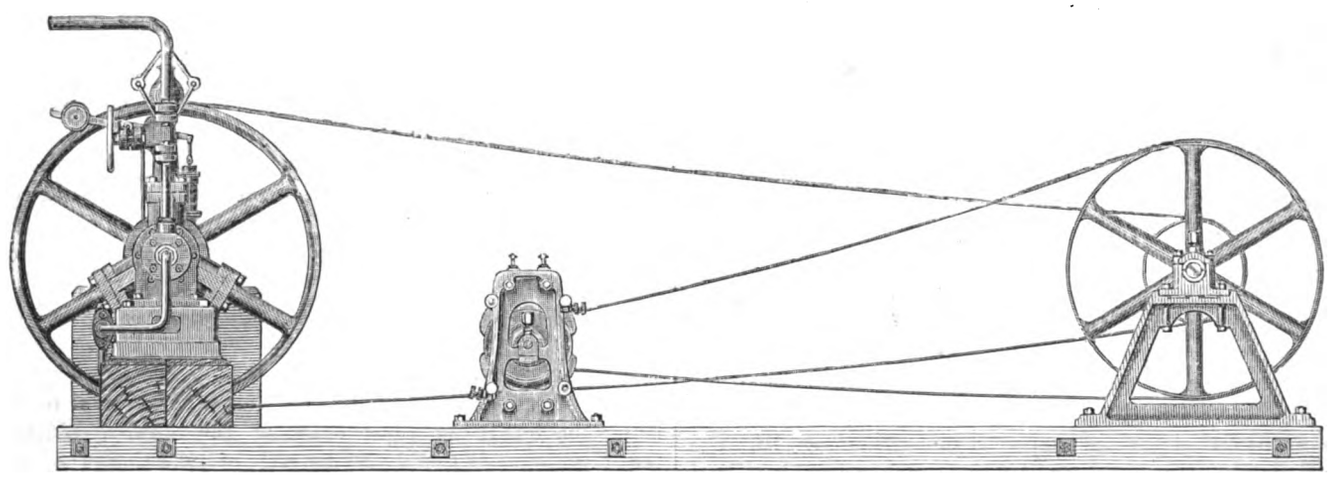
In the field and armature	0·781	horse-power.
In the exterior circuit.....	3·903	„ „
Or a total of.....	4·684	„ „

In order to ascertain the efficiency of the system the following observations of the charge and discharge were taken during a run of 6½ hours:—

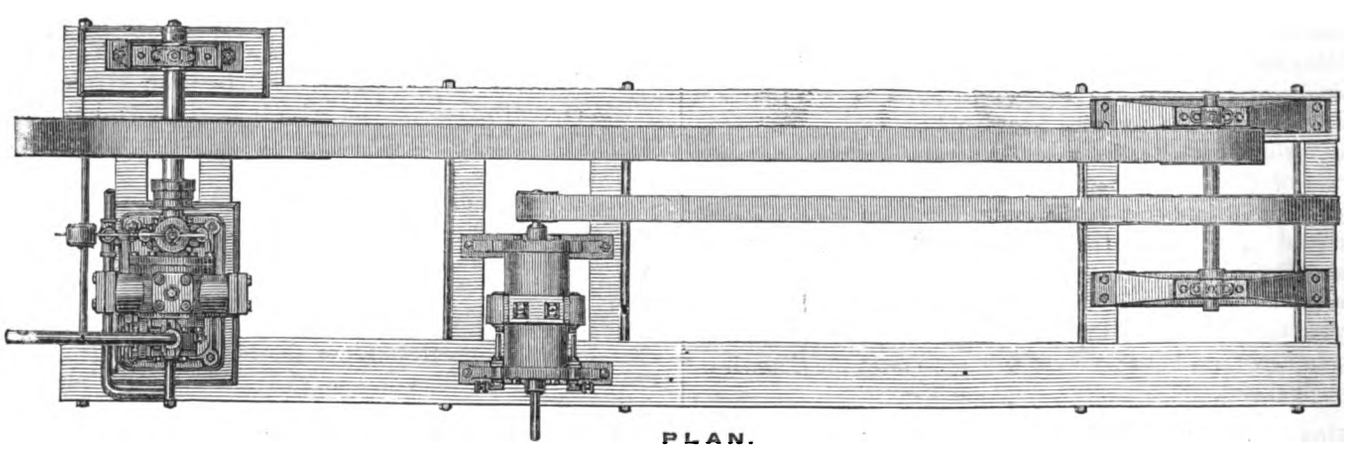
The quantity of water passed was 7,700 gallons. The pressure was assumed to be 660lb. to the square inch, owing to our machine being 80ft. above the main, where the pressure is said to be 700lb. This quantity of water should be capable of 58·138 horse-power-hours of work.

The total observed electrical horse-power was equal to 30·446 hours; therefore, the loss in friction, and inefficient incidence of thrust upon the crank of the engine, owing to the inelastic nature of the medium, would be about 48·642 per cent., and the efficiency 51·358 per cent. (I mean by inefficient incident of thrust that at the beginning and end of each stroke of the pistons the force is principally exerted on the bearings).

The total charge during the 6½ hours at 15 amperes amounts to 97·5 ampere-hours, and the output from the accumulators as measured by a sulphate of copper voltameter was 88·128 ampere-hours, the loss being 9·61 per cent. in volume, and the loss in pressure, or the difference between the potential of the dynamo charge of 194 volts and that of the accumulator discharge of 154·46 volts, is 20·45 per cent. The hydraulic machine has been in daily use for 14 months without interruption.



ELEVATION.



PLAN.

Hydraulic Motor and Gramme Machines.

Digitized by Google

Summary of figures:—

		Horse-power.
Theoretical horse-power of water..		59·29
Electrical horse-power.....	30·4505	59·29
Loss	28·8395	
Efficiency	51·358%	
Electrical horse-power.....		30·4505
Current circulating internally.....	5·0765	30·4505
External or useful current	25·374	
External current		25·374
Return from accumulators	18·247	25 374
Loss	7·127	
Loss		7·127
Difference between dynamo and accumulator potential	5·187	7·127
Loss in accumulator from overcharge and internal leakage ...	1·940	

The horse-power of the electricity generated by the dynamo is estimated from the observed potential and volume of current, and was not measured, as was the discharge, from the accumulators. The figures given are not therefore precisely accurate, but are based on the mean readings of the measuring instruments, and it is also possible that the pressure at the motor while running is overestimated, because our connection with the main is through 120ft. of small pipe. Should this be found to be the case the necessary correction can easily be made.

P.S.—Since the above was written the mean water pressure has been ascertained to be 650lb. The efficiency of the motor is therefore 52·36 per cent. instead of 51·35 per cent.

SOME ENGLISH CENTRAL LIGHTING STATIONS.

V.—LEAMINGTON.
